of Questar Gas Company, the Division of )	
Public Utilities, and Utah Clean Energy for )	
the Approval of the Conservation Enabling)	
Tariff Adjustment Option and Accounting)	
Orders )	

#### SURREBUTTAL TESTIMONY OF

# DANIEL G. HANSEN

### OF

# CHIRISTENSEN ASSOCIATES ENERGY CONSULTING, LLC

August 31, 2007

## 1 I. Introduction

# 2 Q. Please state your name, title, and business address.

- 3 A. My name is Daniel G. Hansen. I am a Vice President at Laurits R.
- 4 Christensen Associates, Inc. My business address is Suite 700, 4610 University
- 5 Avenue, Madison, Wisconsin, 53705.

#### 6 Q. Have you testified in this proceeding before?

- 7 A. Yes. On behalf of the Utah Division of Public Utilities (DPU), I filed
- 8 testimony on June 1, 2007 with an accompanying report on natural gas decoupling
- 9 mechanisms used in the United States (the "Hansen Report"); and I filed rebuttal
- 10 testimony on August 8, 2007. My educational and business background may be
- 11 found in Exhibit 6.2 of the June 1, 2007 testimony.

#### 12 **Q.** What is the purpose of your testimony?

- 13 A. On behalf of the DPU, I am responding to the rebuttal testimonies of Mr.
- 14 Kevin Higgins, witness for the Utah Association of Energy Users (UAE), and Dr.
- 15 David Dismukes, witness for Utah Committee of Consumer Services, both filed on
- 16 August 8, 2007.
- 17 Q. How is your testimony organized?
- 18 A. The remainder of my testimony is organized as follows:
- Section II: Discussion of Mr. Higgins's Rebuttal Testimony
- Section III: Discussion of Dr. Dismukes's Rebuttal Testimony
- Section IV: Summary and Recommendations
- 22 Q. What are the conclusions of your testimony?

23	A.	Mr. Higgins and Dr. Dismukes concluded that the Commission should
24		disregard the conclusion reached in Section 5.2 of Hansen Report, which is that the
25		Conservation Enabling Tariff (CET) is not likely to lead to the shifting of risk
26		between Questar Gas Company (Questar Gas) and its ratepayers. After reviewing
27		their testimony, I have found that their conclusions are without merit.
28		Mr. Higgins improperly summarized the Hansen Report; he incorrectly
29		believed that the test applied in Section 5.2 is "arbitrary and unduly restrictive"
30		(Higgins, August 8, 2007, p. 6); and he incorrectly categorized the CET deferral
31		effects associated with declining use per customer as a shift of risk from Questar Gas
32		to its ratepayers.
33		Dr. Dismukes testified that the statistical model presented in Section 5.2 of the
34		Hansen Report "is more than likely fraught with a variety of data, measurement, and
35		estimation problems" (Dismukes, August 8, 2007, p. 12), but he failed to specifically
36		identify even one of those problems. He continued by asserting that the published
37		literature contains many examples illustrating that the results of Section 5.2 are
38		implausible. However, the only result that is based on a credible analysis of Utah
39		natural gas data (which is also from the most recent study listed) reaches the same
40		conclusion as the Hansen Report: that there is no statistically significant relationship
41		between price and usage levels for residential natural gas customers in Utah.
42		(Bernstein & Griffin, 2005 Report, pp. 88-89.)
43		I therefore maintain the conclusion that I reached in both the Hansen Report
44		and my rebuttal testimony filed on August 8, 2007 that the CET will not shift risk
45		from Questar Gas to its ratepayers.

46	II.	Discussion	of Mr.	Higgins's	Rebuttal	Testimony
----	-----	------------	--------	-----------	----------	-----------

#### 47 Q. Please describe the rebuttal testimony of Mr. Higgins.

A. After examining my report filed on June 1, 2007 (the "Hansen Report"), Mr.
Higgins disputed the analysis and conclusions contained in Section 5.2 of the report,
writing that my "conclusion is overreaching and not adequately supported by the
analysis" (Higgins, August 8, 2007, p. 4.) and that the theory underlying the analysis
is "arbitrary and unduly restrictive." (Id., p. 6.)

#### 53 Q. Please describe Section 5.2 of the Hansen Report.

54 A. Section 5.2 presents the results of a statistical analysis of the relationship 55 between GS-1 use per customer and weather conditions, economic conditions, the 56 commodity price, and a time trend. The purpose of the analysis was to determine 57 whether changes in economic conditions and/or the commodity price affect GS-1 use 58 per customer, and therefore whether the CET shifts risks associated with these factors 59 from Questar Gas to its ratepayers. The analysis found no statistically significant 60 relationship between annual GS-1 use per customer and economic conditions or the 61 commodity price. I therefore concluded that the CET will not shift risk that can be 62 attributed to these factors from Questar Gas to its ratepayers.

#### 63 Q. Does Mr. Higgins correctly describe the Hansen Report?

- A. No. His inaccurate descriptions of the Hansen Report are made most apparent
  on page 7 of his testimony (bold emphasis added):
- Dr. Hansen <u>deems</u> that revenue decoupling will convey **no reduction in risk to QGC** unless GS-1 usage per customer can be shown to vary significantly
   with changes in the natural gas price or changes in Utah economic conditions

69	- irrespective of any other factors. Dr. Hansen thus rules out, by definition,
70	any adjustments to QGC's rate of return to reflect reduced risk from
71	decoupling which may be attributable to variables other than commodity
72	price or the Utah economy.
73	As the bolded text indicates, Mr. Higgins has misconstrued the analysis in Section 5.2
74	to be about risk reductions for Questar Gas as opposed to risk shifting from Questar
75	Gas to its ratepayers. In fact, Section 5.2 does not purport to examine whether the
76	CET will reduce Questar Gas's risk, nor does it reach any conclusions regarding
77	whether reductions in Questar Gas's risk that can be attributed to the CET should be
78	accompanied by a reduction in Questar Gas's rate of return.
79	On page 6 of his testimony, Mr. Higgins further emphasizes his apparent
80	confusion on this matter by writing that "Dr. Hansen's test for determining whether a
81	reduction in risk should be recognized in QGC's allowed rate of return is arbitrary
82	and unduly restrictive." (Emphasis added.) Again, Section 5.2 did not examine
83	whether Questar Gas's risk would be reduced by the CET. The Section 5.2 analysis
84	was conducted in an attempt to assess Dr. Dismukes's contention that "the proposed
85	CET would shift the risks associated with changes in price, the economy, and other
86	factors like greater economy-wide energy efficiency, away from the Company and to
87	ratepayers without any offsetting shifts in rates." (Emphasis added; Dismukes, June
88	30, 2006, p. 28.)
89	These statements by Mr. Higgins reveal an apparent inability to understand
90	that some risks can be reduced for one party without increasing risk for another party,
91	as he uses these concepts interchangeably in his testimony.

as he uses these concepts interchangeably in his testimony.

## 92 Q. Can the CET reduce Questar Gas's risk without shifting risk onto its

#### 93 ratepayers?

94 Yes. Section II of my August 8, 2007 rebuttal testimony discusses the issue of A. 95 risk and risk shifting in detail, and the distinction between the two is specifically 96 addressed on pages 15 and 16. Observing that the CET will reduce the variability of 97 Questar Gas's DNG revenues is not sufficient to conclude that the risk to ratepayers 98 will increase. The *source* of the variability (risk) matters – specifically how the 99 source of the variability affects Questar Gas and its ratepayers. A source such as 100 weather, for which a particular outcome (e.g., a cold winter month) causes one party 101 to be better off at the same time as the other party is worse off, will not lead to risk 102 shifting through the CET. Alternatively, sources such as economic conditions or the 103 commodity price, for which outcomes lead both parties to be worse off at the same 104 time, produce the *potential* for the CET to shift risk. The potential is realized if the 105 source of risk leads to changes in class-level use per customer, which can be tested 106 using a statistical model such as the one presented in Section 5.2 of the Hansen 107 Report.

# 108 Q. Are there other instances in which Mr. Higgins appears to misunderstand the 109 Hansen Report?

A. Yes. On page 5, he writes that "Dr. Hansen summarizes his findings by
concluding that weather risk from decoupling exists." Later, in his footnote 2 on page
7, Mr. Higgins adds:

Dr. Hansen also tests for the significance of weather on usage per customer,
but rules out any recognition in rate of return because "methods exist that can

115		mitigate this risk for both the utility and its customers." [Report, p. 23] In
116		fact, QGC's rate design for GS-1 already removes almost all of the weather-
117		related volatility from revenue per customer, even without revenue
118		decoupling.
119		These excerpts indicate that Mr. Higgins either did not understand or selectively
120		quoted from the Hansen Report. He claims that I concluded that "weather risk from
121		decoupling exists," even though I explicitly ruled out such an outcome in Section
122		3.3.3 of the report. He then implies that I am unaware that GS-1 revenues are
123		adjusted for weather even though I specifically referenced Questar Gas's Weather
124		Normalization Adjustment as an example of a mechanism that can reduce risk for
125		both the utility and its ratepayers. (Hansen Report, p. 9.)
126	Q.	Are there any examples of Mr. Higgins mischaracterizing the results of Section
127		5.2 of the Hansen Report?
128	A.	Yes, on page 5 he writes that "The Utah GDP variable coefficient has a
129		negative sign, suggesting (counter-intuitively) that an improvement in economic
129 130		
		negative sign, suggesting (counter-intuitively) that an improvement in economic
130		negative sign, suggesting (counter-intuitively) that an improvement in economic conditions reduces usage per customer," which he later writes "is suggestive of a
130 131		negative sign, suggesting (counter-intuitively) that an improvement in economic conditions reduces usage per customer," which he later writes "is suggestive of a likely (though not unusual) specification problem in his models." (Higgins, p. 6.) He
130 131 132		negative sign, suggesting (counter-intuitively) that an improvement in economic conditions reduces usage per customer," which he later writes "is suggestive of a likely (though not unusual) specification problem in his models." (Higgins, p. 6.) He fails to note that page 24 of Section 5.2 contains the following caveat about the result
<ol> <li>130</li> <li>131</li> <li>132</li> <li>133</li> </ol>		negative sign, suggesting (counter-intuitively) that an improvement in economic conditions reduces usage per customer," which he later writes "is suggestive of a likely (though not unusual) specification problem in his models." (Higgins, p. 6.) He fails to note that page 24 of Section 5.2 contains the following caveat about the result in question: "Again, because of the high correlation of these variables with the time
<ol> <li>130</li> <li>131</li> <li>132</li> <li>133</li> <li>134</li> </ol>		negative sign, suggesting (counter-intuitively) that an improvement in economic conditions reduces usage per customer," which he later writes "is suggestive of a likely (though not unusual) specification problem in his models." (Higgins, p. 6.) He fails to note that page 24 of Section 5.2 contains the following caveat about the result in question: "Again, because of the high correlation of these variables with the time trend variable, we do not believe that these estimates reflect actual customer
<ol> <li>130</li> <li>131</li> <li>132</li> <li>133</li> <li>134</li> <li>135</li> </ol>		negative sign, suggesting (counter-intuitively) that an improvement in economic conditions reduces usage per customer," which he later writes "is suggestive of a likely (though not unusual) specification problem in his models." (Higgins, p. 6.) He fails to note that page 24 of Section 5.2 contains the following caveat about the result in question: "Again, because of the high correlation of these variables with the time trend variable, we do not believe that these estimates reflect actual customer behavior." Mr. Higgins also does not discuss the fact the coefficients on the

138		Higgins's expectations, it is not counter-intuitive. It simply means that, on average,
139		GS-1 customers have not changed their usage levels when economic conditions
140		changed. He is correct that the results for the models that excluded the time trend
141		variable indicated a potential specification problem, but he does not point out that the
142		specification problem appears to be corrected by including the time trend variable.
143	Q.	Earlier, you cited Mr. Higgins's concerns about the methods used in Section 5.2.
144		Please describe the theory underlying the analysis in that section.
145	A.	The theory underlying this analysis is quite simple, and can be described in a
146		few bullet points:
147		• The CET affects ratepayer bills through deferrals.
148		• The CET will only produce deferral activity when class-level revenue per
149		customer deviates from its allowed level.
150		• Deviations in class-level revenue per customer are driven by changes in
151		class-level use per customer.
152		• Therefore, if a factor (such as economic conditions) does not affect class-
153		level use per customer, the CET cannot produce a shift in risk from the
154		utility to its ratepayers due to variation in that factor.
155		For example, Section 5.2 finds that economic conditions are not related to GS-1 use
156		per customer in historical data. This indicates that future changes in economic
157		conditions are not expected to lead to changes in class-level use per customer, and
158		therefore will not lead to any CET deferral activity. In the absence of CET deferral
159		activity, there can be no shift in risk from Questar Gas to its ratepayers.

160		The Hansen Report and subsequent rebuttal testimony add an important caveat
161		to this simple argument: in order for risk shifting to occur, the potential source of risk
162		must make both the utility and its ratepayers worse off at the same time (i.e., the risk
163		must be "in the same direction" for the two parties). Therefore, factors such as the
164		weather do not lead to risk shifting, while factors such as economic conditions and
165		the commodity price may. Pages 5 through 10 of my August 8, 2007 rebuttal
166		testimony describe this argument in more detail.
167	Q.	Is this the test that Mr. Higgins found to be "arbitrary and unduly restrictive"?
168	А.	It is unclear from his testimony whether Mr. Higgins believes that the theory

itself is incorrect, and if so, what aspect he believes to be incorrect. It is clear that
Mr. Higgins objects to the fact that Section 5.2 examined only the potential for risk
shifting due to changes in the commodity price and economic conditions.

172 Q. What other factors does Mr. Higgins believe should have been examined?

173 A. He only lists the downward trend in use per customer as a factor that he 174 believes should have been examined. Indeed, because the models that include only 175 heating degree days (as a proxy for weather conditions) and a time trend variable 176 explain over 96 percent of the variation in GS-1 use per customer, it would be 177 difficult to conceive of very many additional factors that both explain variations in 178 use per customer and have risks that are in the same direction for Questar Gas and its 179 ratepayers. The only factors that I believed had the potential to meet these criteria 180 were economic conditions and the commodity price.

181 Q. Can you describe Mr. Higgins's concern regarding reductions in use per
182 customer over time?

183 A. Yes. His argument is summarized on page 7 of his testimony, which follows184 below:

185	Second, in drawing his policy conclusion that there is no need to consider
186	adjusting rate of return, Dr. Hansen ignores the very evidence that QGC
187	presented in introducing its revenue decoupling proposal at the outset:
188	namely that usage per customer has been declining for over 25 years and this
189	decline reduces QGC's distribution non-gas ("DNG") revenue per customer in
190	between rate cases. Even Dr. Hansen's own regression analysis demonstrates
191	that the "annual time trend" variable is statistically significant in "explaining"
192	the decline in usage per customer. Yet despite the fact that revenue
193	decoupling will insulate QGC's revenue per customer from this downward
194	usage trend, Dr. Hansen concludes that no risk reduction will occur from
195	decoupling, and that no rate of return adjustment is warranted. This
196	conclusion is not only unwarranted, it is difficult to fathom.
197	His argument appears to be this: everyone knows that use per customer is going to go
198	down in the future (independent of any effects associated with economic conditions,
199	commodity prices, or weather conditions). He confirms this view by writing that
200	"GS-1 usage per customer has declined as a function of time [this] was described
201	and demonstrated in detail by QGC from the outset of this proceeding, and is not
202	disputed." (Id., p. 6.) Because of this reduction in use per customer over time,
203	Questar Gas will under-recover DNG revenues in between rate cases in the absence
204	of the CET or the use of a forecast test year. He contends that because the CET will

205 "insulate QGC's revenue per customer from this downward usage trend," Questar
206 Gas's allowed rate of return should be reduced. (Id., p. 7.)

207 **Q.** Do you agree with this view?

208 A. No. I do not regard the observed downward trend in use per customer as a 209 "risk." By definition, risk is associated with an uncertain outcome. The reduction in 210 use per customer is something that has occurred over a long period of time and is 211 expected to occur in the future. Mr. Higgins himself wrote that the reduction in use 212 per customer over time "is not disputed." (Id., p. 6.) Any reduction in use per 213 customer that is *expected* to occur should be accounted for in the design of the GS-1 214 DNG rates. Failing to account for the expected reduction in use per customer when 215 setting rates will, all else equal, lead to under-recovery of the utility's DNG costs and 216 under-payment of DNG revenues by ratepayers. It therefore appears that Mr. Higgins 217 is merely interested in maintaining a transfer of dollars from Questar Gas to its 218 ratepayers by retaining a flawed ratemaking method (i.e., the use of an historical test 219 year in the absence of decoupling).

Q. Has any other testimony been offered that is consistent with your view that
accounting for expected reductions in use per customer does not constitute a
shift in risk from Questar Gas to its ratepayers?

A. Yes. Section VIII of Dr. Dismukes's June 1, 2007 testimony suggested using
a forecast test year to deal with the revenue effects associated with declining use per
customer. As reflected on page 32 of my August 8, 2007 rebuttal testimony, I agree
that a forecast test year is an adequate substitute for the CET in addressing these
effects (but forecast test years do not resolve utility conservation incentive issues as

228		the CET does). Regarding whether the use of a forecast test year shifts risks from the
229		utility to its ratepayers, Dr. Dismukes wrote "most importantly, the current risk
230		associated with changes in sales would remain with the Company and its
231		shareholders, and not shifted to ratepayers." (Dismukes, June 1, 2007, p. 54.) At no
232		point in his detailed discussion of how the use of a forecast test year would work does
233		Dr. Dismukes mention that it would require a reduction in Questar Gas's rate of
234		return.
235		Therefore, Dr. Dismukes and I appear to agree that a rate mechanism that
236		accounts for expected reductions in use per customer over time does not require a
237		reduction in the utility's rate of return. Such a mechanism simply corrects an inequity
238		that was allowed to persist through the use of imperfect ratemaking practices (i.e., the
239		use of an historical test year in the absence of decoupling).
240	Q.	Doesn't the CET also compensate Questar Gas for <i>unexpected</i> changes in use per
240 241	Q.	Doesn't the CET also compensate Questar Gas for <i>unexpected</i> changes in use per customer over time?
	<b>Q.</b> A.	
241	-	customer over time?
241 242	-	customer over time? Yes. There have been, and certainly will continue to be deviations from the
<ul><li>241</li><li>242</li><li>243</li></ul>	-	customer over time? Yes. There have been, and certainly will continue to be deviations from the expected (or average) reduction in use per customer. For example, Section 5.2 of the
<ul><li>241</li><li>242</li><li>243</li><li>244</li></ul>	-	customer over time? Yes. There have been, and certainly will continue to be deviations from the expected (or average) reduction in use per customer. For example, Section 5.2 of the Hansen Report found that GS-1 use per customer declined by approximately 2.3
<ul> <li>241</li> <li>242</li> <li>243</li> <li>244</li> <li>245</li> </ul>	-	customer over time? Yes. There have been, and certainly will continue to be deviations from the expected (or average) reduction in use per customer. For example, Section 5.2 of the Hansen Report found that GS-1 use per customer declined by approximately 2.3 decatherms per year from 1980 through 2005. If the reduction in a particular year
<ul> <li>241</li> <li>242</li> <li>243</li> <li>244</li> <li>245</li> <li>246</li> </ul>	-	customer over time? Yes. There have been, and certainly will continue to be deviations from the expected (or average) reduction in use per customer. For example, Section 5.2 of the Hansen Report found that GS-1 use per customer declined by approximately 2.3 decatherms per year from 1980 through 2005. If the reduction in a particular year (controlling for other factors, such as weather) was actually lower, say 2.7

250	A.	No, because the risk associated with deviations from the trend in use per
251		customer is "in opposite directions" for the utility and its ratepayers. That is, if a
252		forecast test year had been implemented instead of the CET, the goal of the
253		ratemaking process would be to arrive at an unbiased estimate (i.e., as likely to be too
254		high as it is to be too low) of the change in use per customer over time and account
255		for the expected reduction when setting rates. In a particular year, if the reduction in
256		use per customer is smaller than the assumed value, the utility would be better off in
257		the absence of the CET (i.e., it would over-recover DNG revenues relative to the
258		outcome under a forecast test year), but ratepayers would be worse off (i.e., their bills
259		would be higher than they would have been under a forecast test year). However, the
260		outcome could be reversed in the following year. Therefore, the only difference
261		between using a forecast test year and the CET to address declining use per customer
262		is that the CET will smooth out the revenue and bill impacts associated with
263		deviations from the expected reduction in use per customer over time. This should
264		not harm, and may benefit, both the utility and its ratepayers.
265	Q.	How would you summarize Mr. Higgins's rebuttal testimony?
266	A.	Mr. Higgins's conclusions regarding the Hansen Report should be disregarded
267		by the Commission. He did not provide an accurate summary of the analysis and

268 conclusions contained in Section 5.2 of the Hansen Report, he provides no basis for

269 his assertion that the theory underlying the Section 5.2 analysis is "arbitrary and

- 270 unduly restrictive" (Higgins, p. 6.), and his concern about the omission of declining
- 271 use per customer as a source of risk shifting is unwarranted.
- 272 III. Discussion of Dr. Dismukes's Rebuttal Testimony

273	Q.	Please describe Hansen Report's conclusions regarding whether the CET is
274		expected to shift economic or commodity price risks from Questar Gas to its
275		ratepayers.
276	A.	As described in the previous section, the Hansen Report concluded that the
277		CET will not shift economic or commodity price risks from Questar Gas to its
278		ratepayers. The conclusion was based on a statistical analysis of GS-1 use per
279		customer data from 1980 through 2005, which found no statistically significant
280		relationship between use per customer and economic conditions or the commodity
281		price.
282	Q.	Did this finding meet with any opposition in rebuttal testimony?
283	A.	Yes. I have already addressed Mr. Higgins's testimony that the findings are
284		"suggestive of a likely (though not unusual) specification problem in his models."
285		(Higgins, p. 6.) In addition to this, Dr. Dismukes wrote that "the empirical results are
286		completely at odds with about 40 years of academic research and industry practice"
287		(Dismukes, p. 10) and that "it is more than likely fraught with a variety of data,
288		measurement, and estimation problems that make any of the empirical conclusions
289		reached in the study unusable in this proceeding." (Id., p. 12.)
290	Q.	Does Dr. Dismukes explicitly identify any of the problems he believes are
291		"likely" to have affected the statistical analysis?
292	A.	No. Dr. Dismukes did not make any specific comments regarding
293		shortcomings in the data sources or estimation methods used in the analysis.
294	Q.	Does Dr. Dismukes cite any specific results from academic research and industry
295		practice?

296	A.	Yes, he includes Rebuttal Exhibit CCS-1.3R, which contains brief summaries
297		of twenty estimates of price elasticities (i.e., the source of commodity price risk) and
298		twelve estimates of income elasticities (i.e., the source of economic risk). Some of
299		the estimates are taken from the same study, so that there are actually twelve studies
300		of price elasticities and seven studies of income elasticities referenced in the exhibit.
301		In addition, all of the studies of income elasticities also appear on the list of studies of
302		price elasticities.

# 303 Q. Please describe the studies of price elasticities included in Rebuttal Exhibit CCS-

304 **1.3R**.

305 The exhibit sorts the studies in descending order of date. The first study A. 306 included on the list, Bernstein & Griffin (2005), was conducted in 2005 and examines 307 state-level data, including data for the state of Utah. For the next study listed, Hsing 308 (1992), Dr. Dismukes lists a price elasticity for the state of Alaska. It is unclear why 309 he chose to do this, as the Hsing study purports to estimate elasticities for all states 310 except Hawaii. The next four listed results are from a study conducted 18 years ago 311 that examined data from France and West Germany. The remaining studies on the list were conducted between 26 and 56 years ago. Half of the listed results<sup>1</sup> are not 312 313 even related to natural gas price response – they are analyses of residential *electricity* 314 price response, which may be very different from natural gas price response because 315 of the differences in the end uses for which each is used. The summaries of at least 316 four of the results are incorrect: the short-run price elasticity estimated in Houthakker 317 et al (1973) is listed as -0.9, where the correct value (-0.09) is an order of magnitude

<sup>&</sup>lt;sup>1</sup> If the rows of table on Page 1 of Rebuttal Exhibit CCS-1.3R were numbered 1 through 20, the results that are taken from analyses of electricity demand appear on rows 10, 11, 12, 13, 14, 15, 16, 17, 19, and 20.

Daniel G. Hansen

318		smaller; and three of the results from Beierlein, Dunn, & McConnon (1981) that are
319		described as short-run price elasticities are in fact cross-price elasticities (showing the
320		change in electricity demand as the price of natural gas changes).
321		Of the studies listed in Exhibit CCS-1.3R, only the most recent study by
322		Bernstein & Griffin (2005) appears to be relevant to the issue at hand, in that it uses
323		relatively recent data that includes information specific to Utah and attempts to
324		estimate natural gas price elasticities. The Hsing (1992) study included information
325		specific to Utah, but does not produce relevant results for reasons described below. <sup>2</sup>
326	Q.	Did Dr. Dismukes correctly characterize the findings of the Bernstein & Griffin
327		(2005) study?
328	A.	Not really. His summary of a -0.18 short-run price elasticity and a -0.44 long-

However, he fails to note that the study contains <i>state-level</i> results as well as regional results, which are described in Chapter 5 with the associated regression results presented in Appendix D. When examining the price elasticities specifically for Utah, Bernstein &

 $<sup>^{2}</sup>$  At the time that surrebuttal testimony was due, Dr. Dismukes had not yet provided copies of the Mount, Chapman, & Tyrrell (1973) or Wilson (1971) studies, as we had requested. However, the titles of the articles indicate that they relate to electricity demand and not natural gas demand. Therefore, I do not believe that the studies are relevant to this proceeding. If the opportunity to review the studies reveals information that I believe is important to this proceeding, I will provide it in supplemental testimony.

338		More importantly, neither of these estimated price elasticity values for the
339		state of Utah is statistically significantly different from zero. In fact, neither result is
340		even close to being statistically significant. Traditionally, if the "p-value" associated
341		with an estimated coefficient is less than 0.10 or 0.05, the coefficient would be
342		regarded as being statistically significantly different from zero. The p-values
343		associated with the Utah state specific short- and long-run price elasticity estimates
344		are far higher than these traditional standards, at 0.771 and 0.776, respectively, and
345		therefore one should regard these estimates as being no different from zero.
346		In summary, the findings of the Bernstein & Griffin (2005) study are
347		completely consistent with the findings contained in Section 5.2 of the Hansen
348		Report, in that both show no statistically significant relationship between Utah
349		residential natural gas consumption and natural gas prices.
517		residential natural gas consumption and natural gas prices.

This study attempted to examine differences in natural gas price and income elasticities across states. The results are based on five years of data, from 1985 through 1989, for each state except Hawaii (for which no data were available). At the national level, the study estimates a price elasticity of -0.738 and an income elasticity of 0.476 (using the double-log specification). For Utah (based on 1989 data), it estimates a price elasticity of -0.55 and an income elasticity of 0.39.
<ul> <li>350</li> <li>351</li> <li>352</li> <li>353</li> <li>354</li> <li>355</li> <li>356</li> <li>357</li> </ul>	А. <b>Q.</b>	Please describe the Hsing (1992) study. This study attempted to examine differences in natural gas price and income elasticities across states. The results are based on five years of data, from 1985 through 1989, for each state except Hawaii (for which no data were available). At the national level, the study estimates a price elasticity of -0.738 and an income elasticity of 0.476 (using the double-log specification). For Utah (based on 1989 data), it estimates a price elasticity of -0.55 and an income elasticity of 0.39. Do you find these results to be credible?

361 period of time, 1985 through 1989, during which natural gas prices in Utah did not 362 experience much variation. Because the range of experience with prices is fairly 363 narrow during that time, the elasticity estimates may not be representative of response 364 in subsequent years, in which natural gas prices were considerably more volatile. 365 A more important, but also more technical (and therefore less easily 366 conveyed) reason for disregarding the estimates in the Hsing study is because of 367 serious flaws in the methods used. The intent of the study is to examine differences 368 in price elasticities across states. However, the study only estimates one aggregate 369 relationship between use per customer and the natural gas price. Though the data set 370 contains information from 49 states, the estimated price coefficient represents an 371 average, national-level effect (though it does not appear to be properly weighted by 372 state population).

373 In one of the models (the "double-log" model), the estimated coefficient can 374 be directly interpreted as an elasticity. In the other two models (the "General" and 375 "Linear" models) the estimated coefficient must be multiplied by the ratio of the 376 natural gas price divided by the use per customer in order to be interpreted as an 377 elasticity (which is defined as the percentage change in quantity divided by the 378 percentage change in price or income). The study performs this adjustment using the 379 1989 data from each state and interprets the results as showing that the "price 380 elasticities varied widely." (Hsing, p. 256.) In fact, the study has only demonstrated 381 that the ratio of the natural gas price to use per customer has varied widely across 382 states.

Compounding the difficulty in deriving any meaning from the results, Hsing failed to estimate the standard error associated with any of the state-level results. It is therefore impossible for a reader to determine whether the state-level effects are statistically significantly different from one another, or whether they are different from zero.

In addition, Hsing does not employ standard statistical methods for the type of 388 389 data that he uses. The data used in the analysis are referred to as "panel" data, which 390 combines "time series" data (e.g., information across time for one state) and "cross-391 sectional" data (e.g., information across states for one year). Specifically, according to A Guide to Econometrics by Peter Kennedy<sup>3</sup>, "Fixed and random effects models 392 393 are usually employed when the number of cross-sectional units is large and the 394 number of time periods over which those units are observed is small." (Kennedy, p. 395 225.)

396 Bernstein & Griffin (2005), which also employs panel data, uses a fixed 397 effects model, as reflected by the  $s_i$  parameter in first equation on page 59. In order 398 to estimate state-level price elasticities, Bernstein & Griffin interact the state-level 399 variables  $(s_i)$  with the natural gas price variable. (Bernstein & Griffin, p. 60.) In 400 contrast to the methods used in Hsing (1992), this is a valid method for estimating 401 differences in price elasticities across states. It allows the estimate of price 402 responsiveness to vary across states and produces a standard error for each state-level 403 estimate, against which the level of statistical significance of each estimate may be 404 judged.

<sup>&</sup>lt;sup>3</sup> Published by The MIT Press in Cambridge, MA in 1992.

405		As noted above, the valid methods employed by Bernstein & Griffin produced
406		Utah price elasticity estimates that were not statistically significantly different from
407		zero. The results of Hsing (1992) are based on flawed methods and should therefore
408		be disregarded by the Commission.
409	Q.	Please describe the studies of income elasticities included in Rebuttal Exhibit
410		CCS-1.3R.
411	A.	These studies are a subset of those provided regarding price elasticities. The
412		estimate contained in Hsing (1992) should be disregarded for the reasons described
413		above. (That is, all of the problems that I have described for its estimates of price
414		elasticities are equally applicable to its estimates of income elasticities.) Dr.
415		Dismukes lists eight (out of twelve) results that are not related to natural gas usage
416		(they are studies of electricity usage). This leaves only the first three results of the
417		Beierlein, Dunn, & McConnon (1981) study, which uses data for the northeastern
418		United States between 1967 and 1977. In summary, the studies listed on page 2 of
419		Exhibit CCS-1.3R should not be regarded as relevant to the current proceeding, as
420		they incorporate some or all of the following traits: estimates based on flawed
421		methods, data from other locations, elasticity values for industries other than natural
422		gas, and information that is decades out of date.
423	Q.	Dr. Dismukes is concerned that "if the Division's results are accepted, then
424		increases in natural gas prices since the winter of 2000-2001 have had no
425		material impact on customer usage." (Dismukes, p. 10.) Is there any evidence
426		that such an impact occurred?

427	A.	Perhaps surprisingly, there is no evidence that the large increases in natural
428		gas prices during that winter led to significant reductions in customer usage. Dr.
429		Dismukes's hypothesis can be explicitly tested by expanding upon the analysis
430		contained in Section 5.2 of the Hansen Report.
431		The statistical model presented in column 6 of Table 1B of the Hansen Report
432		shows that including only heating degree days and a time trend variable accounts for
433		96.4 percent of the variation in GS-1 use per customer during the 1980 through 2005
434		time period. In order for Dr. Dismukes's hypothesis to be correct, the high natural
435		gas prices that began in the winter of 2000-2001 would need to cause one of two
436		effects to occur in the subsequent years: a reduction in the average use per customer,
437		or in an increase in the <i>rate</i> of reduction of use per customer (i.e., a more steeply
438		declining time trend).
439		DPU Exhibit 6.1SR shows the findings associated with this analysis. Column
440		1 replicates the results from Table 1B in Section 5.2 of the Hansen Report. Column 2
441		shows the results when an indicator variable is added for the years 2001 through

2005. The coefficient for this variable is therefore an estimate of the average change
in GS-1 use per customer after December 2000, controlling for the effects of weather
and the overall decline in use per customer since 1980. The estimated coefficient is
negative (which indicates a reduction in use per customer following the year 2000),

but is not even close to being statistically significantly different from zero. The pvalue for this coefficient is 0.705. (Recall that p-values less then 0.10 or 0.05 are
traditionally considered as representing statistical significance.) The conclusion from
this model is therefore that GS-1 use per customer was not, on average, lower from

2001 through 2005 than it was from 1980 through 2000, controlling for the effects ofweather and the downward trend in use per customer.

452 Column 3 of DPU Exhibit 6.1SR shows the results of a test for whether the 453 rate of decline in use per customer changed in 2001 to 2005 relative to 1980 to 2000. 454 This is tested using an "interaction" variable that is defined as the product of the 455 annual time trend variable and the indicator variable for the years 2001 to 2005. To 456 be consistent with Dr. Dismukes's hypothesis that increases in natural gas prices had 457 a material effect on customer usage, the estimated coefficient on this variable needs to 458 be negative (i.e., customers are reducing usage at a faster rate than they were prior to 459 2001) and statistically significantly different from zero. The results show an estimated coefficient that is negative, but is not statistically significantly different 460 461 from zero (with a p-value of 0.735). Therefore, the conclusion from this model is that 462 the rate of reduction in use per customer was not statistically significantly different 463 from 2001 to 2005 than it was from 1980 to 2000.

# 464 Q. Doesn't your analysis build upon a model to which Dr. Dismukes has already 465 objected?

A. Yes, so it is worth addressing the potential concerns that he raised in his
rebuttal testimony. The data used in the analysis (use per customer and heating
degree day data) are taken directly from Questar Gas's databases. That would seem
to remove Dr. Dismukes's concern about potential measurement problems for the
models presented in DPU Exhibit 6.1SR. In addition, though he may assert that
"estimation problems" continue to exist, the model presented in column 1 of DPU
Exhibit 6.1SR demonstrates a relationship between use per customer and weather and

Daniel G. Hansen

473		a time trend that even Mr. Higgins described as "obvious." <sup>4</sup> The models shown in the
474		next two columns simply add variables that are a function of time (and therefore not
475		subject to measurement error) to test whether use per customer differed either on
476		average, or in terms of the rate of change, following the increases in natural gas prices
477		that began in the winter of 2000 to 2001. If customer response to the increase in
478		prices had been sufficiently large to affect class-level use per customer between 2001
479		and 2005, these models would have been able to identify the response with
480		statistically significant estimates. No such effect was found.
481	Q.	Do your results indicate that customers were not worse off after the large
482		increases in prices, or were somehow indifferent to them?
483	A.	Not at all. The results do not diminish the hardship that increases in natural
484		gas prices place on customers. On the contrary, the results indicate that customers
485		appear to value the services that natural gas delivers so highly that even a fifty
486		percent increase in the delivered price (between January 2000 and January 2001) does
487		not produce a significant change in class-level use per customer.
488	Q.	Dr. Dismukes also points out that Questar Gas "estimates a -0.06 price elasticity
489		of demand that is derived from its load forecasts supporting its Integrated
490		Resource Plan ("IRP"). (Page 11) Doesn't this contradict your findings?
490 491	A.	
	A.	Resource Plan ("IRP"). (Page 11) Doesn't this contradict your findings?

<sup>&</sup>lt;sup>4</sup> Mr. Higgins wrote: "The only clear implications of Dr. Hansen's statistical results are the obvious conclusion that GS-1 usage per customer is a function of temperature and a confirmation that GS-1 usage per customer has declined as a function of time. The latter phenomenon was described and demonstrated in detail by QGC from the outset of this proceeding, and is not disputed." (Higgins, p. 6.)

Daniel G. Hansen

494		elasticity value was simulated rather than estimated, and Questar Gas does not report
495		the standard error associated with this simulated value. That is, the elasticity value
496		was generated by plugging values into a model, as opposed to being directly
497		estimated from data. I cannot therefore say with any statistical certainty whether the
498		estimated value is statistically significantly different from zero.
499		In any case, in discussing this estimate Dr. Dismukes wrote that it "appears to
500		be small" (p. 11), even though he had earlier found the value to be sufficient for use
501		in a statistical re-coupling approach that he recommended in his June 30, 2006
502		testimony. <sup>5</sup>
503		Remember, Dr. Dismukes is not only proposing that customer price response
504		exists for Utah's GS-1 customers (which is a reasonable hypothesis to test), but that
505		the <i>level</i> of price response – and therefore the magnitude of the shift in risk from
<b>T</b> O 6		Questar Gas to its rate payers $-$ is so large that the CET should be discontinued.
506		Questar Sus to his fatepayers - is so harge that the ODF should be discontinued.

<ul> <li>507</li> <li>508</li> <li>509</li> <li>510</li> <li>511</li> <li>512</li> <li>513</li> </ul>	-	How would you summarize Dr. Dismukes's criticisms of the estimates contained in Section 5.2 of the Hansen Report? Dr. Dismukes asserted that the analysis is "more than likely fraught with a variety of data, measurement, and estimation problems" (page 12), but provided no indication of what those problems might be. Dr. Dismukes asserted that the price increases during the winter of 2000 to 2001 <i>must</i> have reduced customer usage levels, but provided no evidence that it

<sup>&</sup>lt;sup>5</sup> He wrote: "The elasticity estimates (and trend adjustment) could come from the Company's most recent IRP that includes an income elasticity of 0.05 and a price elasticity of -0.06 on a use per customer basis." (Dismukes, June 30, 2006, p. 11.)

516		Dr. Dismukes provided twenty estimates of price elasticities from published
517		literature as evidence that the results of the Hansen Report are not plausible.
518		However, virtually all of these results are not applicable to the current proceeding:
519		five of the estimates use data from Europe, ten of the estimates do not examine
520		natural gas data, and fourteen estimates are taken from studies that are more than
521		twenty-five years out of date. Two studies that he cites examine natural gas usage in
522		the state of Utah: one is based on flawed methods and uses only data from 1985 to
523		1989 (when very little variation in natural gas prices occurred relative to recent
524		years); and the other study reaches the same conclusion as the Hansen Report: that
525		there is no statistically significant relationship between residential usage and price.
526	Q.	Please describe Dr. Dismukes's concern about the relationship between the CET
	-	-
527	-	and the WNA.

528 529 530 531 532	-	and the WNA. On pages 16-17 of his testimony, Dr. Dismukes provides an excerpt from the Hansen Report regarding the relationship between decoupling and weather normalization mechanisms, that "[d]ecoupling mechanisms improve the functioning of weather normalization mechanisms by 'cleaning up' any errors in the definition of normal weather." (Hansen Report, p. 14.) He believes that this indicates a problem
528 529 530 531 532 533	-	and the WNA. On pages 16-17 of his testimony, Dr. Dismukes provides an excerpt from the Hansen Report regarding the relationship between decoupling and weather normalization mechanisms, that "[d]ecoupling mechanisms improve the functioning of weather normalization mechanisms by 'cleaning up' any errors in the definition of normal weather." (Hansen Report, p. 14.) He believes that this indicates a problem with the CET because "the motivating factor for its adoption was to promote DSM,

537	A.	No. Nowhere in the Hansen Report or my subsequent rebuttal testimony did I
538		identify a deficiency in the definition of normal weather used in the WNA. <sup>6</sup> In
539		addition, I have not asserted that the purpose of the CET is to "correct for deficiencies
540		in the Weather Normalization Adjustment." However, it seems unwise to propose
541		that the CET should be abolished because it has the ability to correct for any
542		problems that may exist in the definition of normal weather used in the WNA. It is as
543		though he is suggesting that a program should not be approved if it produces benefits
544		that are unrelated to its primary purpose.
545	Q.	Dr. Dismukes cites the observed deferrals for the CET to date as "an alternative
546		measure for the magnitude of risk shifting between GS-1 customers and the
547		Company." (Id., p. 13.) Do you agree with this conclusion?
548	A.	No. The <i>source</i> of the deferrals matter; and Dr. Dismukes has made no
548 549	A.	No. The <i>source</i> of the deferrals matter; and Dr. Dismukes has made no attempt to identify the cause of the deferrals.
	A.

For example, it could be that the deferral represents the effects associated with ongoing declines in GS-1 use per customer. Dr. Dismukes has testified that Questar Gas should be compensated for expected declines in use per customer through the use of a forecast test year, and that doing so does not represent a shift in risk.
<ul> <li>549</li> <li>550</li> <li>551</li> <li>552</li> <li>553</li> <li>554</li> </ul>	A.	attempt to identify the cause of the deferrals. For example, it could be that the deferral represents the effects associated with ongoing declines in GS-1 use per customer. Dr. Dismukes has testified that Questar Gas should be compensated for expected declines in use per customer through the use of a forecast test year, and that doing so does not represent a shift in risk. The expected CET deferral associated with declining use per customer can be
<ul> <li>549</li> <li>550</li> <li>551</li> <li>552</li> <li>553</li> <li>554</li> <li>555</li> </ul>	A.	attempt to identify the cause of the deferrals. For example, it could be that the deferral represents the effects associated with ongoing declines in GS-1 use per customer. Dr. Dismukes has testified that Questar Gas should be compensated for expected declines in use per customer through the use of a forecast test year, and that doing so does not represent a shift in risk. The expected CET deferral associated with declining use per customer can be estimated from information presented earlier. This amount is equivalent to the

<sup>&</sup>lt;sup>6</sup> Errors in setting the definition of normal weather used in a weather normalization mechanism will skew payments toward either the utility or its ratepayers, depending upon the direction of the error.

558		Suppose that there are 820,000 GS-1 customers (the approximate average
559		number between July 2006 and April 2007), that use per customer declines 2.3 Dth
560		per year (consistent with the time trend coefficient estimate shown in DPU Exhibit
561		6.1SR), and that the DNG price per Dth is \$1.85 (in between the first block prices for
562		the winter and summer seasons). Under these conditions, one would expect a CET
563		deferral of about \$3.5 million, if the reduction occurred on January 1 <sup>st</sup> and lasted the
564		full year. If the reduction instead occurred steadily over the year, a deferral of about
565		\$1.75 million would be expected (half of the \$3.5 million).
566		As this (admittedly somewhat crude) estimate of the expected effect
567		associated with declining use per customer shows, one can expect the CET to produce
568		deferrals in Questar Gas's favor that are of the same magnitude as the observed
569		deferrals for this reason alone.
570	Q.	Could the observed deferrals have been caused by a shifting of commodity price
<b>571</b>		
571		or economic risks?
571	A.	or economic risks? No. Even if one does not accept the conclusions of the Hansen Report
	A.	
572	A.	No. Even if one does not accept the conclusions of the Hansen Report
572 573	A.	No. Even if one does not accept the conclusions of the Hansen Report regarding the CET's potential for shifting these risks onto ratepayers, the conditions
572 573 574	A.	No. Even if one does not accept the conclusions of the Hansen Report regarding the CET's potential for shifting these risks onto ratepayers, the conditions required in order for ratepayers to be made worse off by these risk shifts are not
572 573 574 575	A.	No. Even if one does not accept the conclusions of the Hansen Report regarding the CET's potential for shifting these risks onto ratepayers, the conditions required in order for ratepayers to be made worse off by these risk shifts are not present.
572 573 574 575 576	A.	No. Even if one does not accept the conclusions of the Hansen Report regarding the CET's potential for shifting these risks onto ratepayers, the conditions required in order for ratepayers to be made worse off by these risk shifts are not present. Commodity price risk adversely affects ratepayers when they reduce usage
572 573 574 575 576 577	A.	No. Even if one does not accept the conclusions of the Hansen Report regarding the CET's potential for shifting these risks onto ratepayers, the conditions required in order for ratepayers to be made worse off by these risk shifts are not present. Commodity price risk adversely affects ratepayers when they reduce usage levels in response to increases in prices. However, Questar Gas's GS-1 rates

581		according to data from the Bureau of Labor Statistics, Utah unemployment rates are
582		lower now than they were in July 2006.
583		Therefore, the conditions required for ratepayers to be made worse off by
584		these risks have not existed during the CET pilot.
585	Q.	Does Dr. Dismukes acknowledge the ratepayer risk inherent in GS-1 DNG rates?
586	A.	No. The GS-1 DNG rates contain risk for ratepayers, in that any fluctuation in
587		usage levels changes the amount that they pay for fixed DNG costs. Another way of
588		looking at the observed deferral could therefore be that it offsets ratepayer under-
589		payment for DNG services. In subsequent periods, usage levels could lead to
590		ratepayer over-payment for DNG services, which the CET would also correct.
591		IV. Summary and Recommendations
592	Q.	Please summarize your surrebuttal testimony.
592 593	<b>Q.</b> A.	Please summarize your surrebuttal testimony. Mr. Higgins and Dr. Dismukes concluded in their rebuttal testimony that the

However, Mr. Higgins improperly summarized the Hansen Report; he incorrectly believed that the test applied in Section 5.2 is "arbitrary and unduly restrictive" (Higgins, p. 6); and he incorrectly categorized the CET deferral effects associated with declining use per customer as a shift of risk from Questar Gas to its

604		and estimation problems" (Dismukes, p. 12), but he failed to specifically identify
605		even one of those problems. He continued by asserting that the published literature
606		contains many examples illustrating that the results of Section 5.2 are implausible.
607		However, the only study that he presents that credibly analyzes Utah natural gas data
608		(which is also the most recent study listed by more than a decade) reaches the same
609		conclusion as the Hansen Report: that there is not a statistically significant
610		relationship between price and usage levels for residential natural gas customers in
611		Utah.
612	Q.	What are your recommendations based on this testimony?
613	A.	The Commission should disregard the criticisms of Hansen Report contained
614		in the testimony of Mr. Higgins and Dr. Dismukes. I continue to recommend that the
615		Commission retain the CET.
616	Q.	Does this conclude your testimony?

617 A. Yes.
