

1 **Q. Please state your name, business address and present position with**
2 **PacifiCorp (the Company).**

3 A. My name is Mark Widmer, my business address is 825 N.E. Multnomah, Suite
4 800, Portland, Oregon 97232, and my present position is Manager, Regulation.

5 **Qualifications**

6 **Q. Briefly describe your education and business experience.**

7 A. I received an undergraduate degree in Business Administration from Oregon State
8 University. I have worked for PacifiCorp since 1980 and have held various
9 positions in the power supply and regulatory areas. I was promoted to my present
10 position in March 2001.

11 **Q. Please describe your current duties.**

12 A. I am responsible for the coordination and preparation of net power cost and
13 related analyses used in retail price filings. In addition, I represent the Company
14 on power resource and other various issues with intervenor and regulatory groups
15 associated with the six state regulatory commissions to whose jurisdiction we are
16 subject.

17 **Summary of Testimony**

18 **Q. Will you please summarize your testimony?**

19 A. I will present the results of the production cost model study for the 12-month
20 future test period ending March 31, 2006. I will describe the Company's
21 production cost model, the Generation and Regulation Initiatives Decision Tools
22 (GRID) model, which is used to calculate net power costs. I will provide
23 information on how input data is normalized in GRID and the rationale for doing

1 so. I will describe the change in hydro modeling associated with the VISTA hydro
2 model and finally, I will describe the Aquila Hydro Hedge and the Company's
3 proposed method of including the associated costs and benefits in rates.

4 **Net Power Cost Results**

5 **Q. What are the results of the Company's test year net power cost study?**

6 A. Total Company net power costs for the 12-month period ending March 31, 2006
7 are approximately \$745 million Total Company. In comparison, actual results for
8 the 12 month period ending May 2004 were approximately \$687 million.

9 **Q. How does this compare with the level currently included in rates?**

10 A. Test period net power costs are approximately \$233 million higher than the \$512
11 million included in base rates from the Docket No. 03-2035-02 Order. The bulk
12 of the cost increases are caused by the 4.4 million MWh increase in net system
13 load (\$157 million, which represents 67 percent of the total \$233 million
14 increase), the increase in fuel prices (\$28 million), the loss of revenue from the
15 expiration of the Puget and CDWR wholesale sales contracts (\$16 million), the
16 expiration of the existing Grant Mid Columbia purchase power contract and the
17 new Grant County contract (\$3 million), a contractual price increase for the
18 Biomass QF contract (\$7 million), which would partially be assigned to other
19 jurisdiction under the revised protocol, a contractual price increase for the
20 Hermiston purchase (\$6 million) and the renegotiated Sunnyside contract (\$5
21 million).

22 **Q. What is the impact of the net power cost increase on a Utah allocated basis?**

23 A. In Docket No. 03-2035-02, the Commission authorized the Company to recover

1 approximately \$202 million in rates. The Utah share of the Company's proposed
2 net power costs is approximately \$309 million or an increase of \$107 million
3 from the previous authorized level.

4 **Determination of Net Power Cost**

5 **Q. Please explain net power costs.**

6 A. Net power costs are defined as the sum of fuel expenses, wholesale purchase
7 expenses and wheeling expenses, less wholesale sales revenue.

8 **Q. Were the proposed net power costs which you have sponsored developed**
9 **with the same production dispatch model used in the Company's last Utah**
10 **filing?**

11 A. Yes, with one exception. The Company's proposed net power costs were
12 developed using the updated version 2.3 of the GRID model. This version
13 provides additional tools to make it easier to create and compare scenarios. There
14 have also been some improvements in the calculation logic. However, the core
15 calculation logic is the same. One feature of note is the quick start credit for
16 uncommitted peaking units that has been added to GRID operating reserve logic.
17 This feature resolves a model deficiency that was identified in Docket No. 03-
18 2035-02 where the parties entered into a Stipulation requiring the Company to
19 make specific improvements to the GRID model.

20 **Q. With the exception of normal updates, are there any significant changes in**
21 **the inputs to the model?**

22 A. Yes, there is a change to the methodology for developing the hydro inputs. In my
23 following testimony, I'll describe hydro inputs in more detail.

1 **Q. Please explain how the Company calculated net power costs.**

2 A. Net power costs were calculated for a future test period based on projected data
3 using the GRID model. For each hour in the forecast period the model simulates
4 the operation of the power supply portion of the Company under a variety of
5 stream flow conditions. The results obtained from the various stream flow
6 conditions are averaged and the appropriate cost data is applied to determine an
7 expected net power cost under normal stream flow and weather conditions for the
8 test period.

9 **Q. Please explain how GRID projects future net power costs.**

10 A. The development of expected net power costs begins with the selection of either a
11 future or historic test period. This filing is a future test period. I have divided the
12 description of the power cost model into three sections, which follow below:

- 13 1. The model used to calculate net power costs.
- 14 2. The model inputs.
- 15 3. The model output.

16 **The GRID Model**

17 **Q. Please describe the GRID model?**

18 A. The GRID model is the Company's hourly production dispatch model, which the
19 Company uses to calculate net power costs. It is a server-based application that
20 uses the following high-level technical architecture to calculate net power costs:

- 21 – An Oracle-based data repository for storage of all inputs
- 22 – A Java-based software engine for algorithm and optimization processing
- 23 – Outputs that are exported in Excel readable format

1 – A web browser-based user interface

2 Based on requests by regulatory staffs and intervenors, the Company provides the
3 model on a stand-alone personal computer.

4 **Q. Please describe the methodology employed to calculate net power costs in this**
5 **docket.**

6 A. Net power costs are calculated hourly using the GRID model. The general steps
7 are as follows:

8 1. Determine the input information for the calculation, including retail load,
9 wholesale contracts, market prices, thermal and hydro generation capability,
10 fuel costs, transmission capability and expenses

11 2. The model calculates the following pre-dispatch information:

12 – Thermal availability

13 – Thermal commitment

14 – Hydro shaping and dispatch

15 – Energy take of long term firm contracts

16 – Energy take of short term firm contracts

17 – Reserve requirement and allocation between hydro and thermal resources

18 3. The model determines the following information in the Dispatch
19 (optimization) logic, based on resources, including contracts, from the pre-
20 dispatch logic:

21 – Optimal thermal generation levels, and fuel expenses

22 – Expenses (revenues) from firm purchase (sales) contracts

- 1 – System balancing market purchases and sales necessary to balance and
2 optimize the system and net power costs taking into account the
3 constraints of the Company’s system
- 4 – Expenses for purchasing additional transmission capability
- 5 4. Model outputs are used to calculate net power costs on a total Company basis,
6 incorporating expenses (revenues) of purchase (sales) contracts that are
7 independent of dispatched contracts, which are determined in step 3.

8 The main processors of the GRID model are steps 2 and 3.

9 **Q. Please describe in general terms, the purposes of the Pre-dispatch and**
10 **Dispatch processes.**

11 A. The Dispatch logic is a linear program (LP) optimization module, which
12 determines how the available thermal resources should be dispatched given load
13 requirements, transmission constraints and market conditions, and whether market
14 purchases (sales) should be made to balance the system. In addition, if market
15 conditions allow, market purchases may be used to displace more expensive
16 thermal generation. At the same time, market sales may be made either from
17 excess resources or market purchases if it is economical to do so under market
18 and transmission constraints.

19 **Q. Does the Pre-dispatch logic provide thermal availability and system energy**
20 **requirements for the Dispatch logic?**

21 A. Yes. Pre-dispatch, which occurs before the Dispatch logic, calculates the
22 availability of thermal generation, dispatches hydro generation, schedules firm
23 wholesale contracts, and determines the reserve requirement of the Company’s

1 system. In my following testimony, I'll describe each of the calculations in more
2 detail.

3 **Generating resources in Pre-Dispatch**

4 **Q. Please describe how the GRID model determines thermal availability and**
5 **commitment.**

6 A. The Pre-dispatch logic reads the input regarding thermal generation by unit, such
7 as nameplate capacity, normalized outage and maintenance schedules, and
8 calculates the available capacity of each unit for each hour. The model then
9 determines the hourly commitment status of thermal units based on planned
10 outage schedules, and a comparison of operating cost vs. market price if the unit
11 is capable of cycling up or down in a short period of time. The commitment
12 status of a unit indicates whether it is economical to bring that unit online in that
13 particular hour. The availability of thermal units and their commitment status are
14 used in the Dispatch logic to determine how much may be generated each hour by
15 each unit.

16 **Q. How does the model shape and dispatch hydro generation?**

17 A. In the Pre-dispatch logic, the Company's available hydro generation from each
18 non-run of river project is shaped and dispatched by hour within each month in
19 order to maximize usage during peak load hours. The monthly shape of a non-run
20 of river project is based on the hourly retail load and market prices in a month,
21 and incorporates minimum and maximum flow for the project to account for
22 environmental constraints. The dispatch of the generation is flat in all hours of
23 the month for run of river projects. The hourly dispatched hydro generation is

1 used in the Dispatch logic to determine energy requirements for thermal
2 generation and system balancing transactions.

3 **Wholesale contracts in Pre-Dispatch**

4 **Q. Does the model distinguish between short-term firm and long-term firm**
5 **wholesale contracts in the Pre-dispatch logic?**

6 A. Yes. Short-term firm contracts are block energy transactions with standard terms
7 and a term of one year or less in length. In contrast, many of the Company's
8 long-term firm contracts have non-standard terms that provide different levels of
9 flexibility. For modeling purposes, long-term firm contracts are categorized as
10 one of the following seven archetypes based on contract terms:

- 11 – Energy Limited (shape to price or load): The energy take of these contracts
12 have minimum and maximum load factors. The complexities can include
13 shaping (hourly, annual), exchange agreements, and call/put optionality.
- 14 – Generator Flat: The energy take of these contracts is tied to specific
15 generators and is the same in all hours, which takes into consideration plant
16 down time. There is no optionality in these contracts.
- 17 – Generator Optional: The energy take of these contracts is also tied to specific
18 generators but is dispatched as generators with flexibility. They can be either
19 hydro or thermal generation.
- 20 – Flat (or Fixed): These contracts have a fixed energy take in all hours of a
21 period.
- 22 – Complex: The energy take of one component of a complex contract is tied to
23 the energy take of another component in the contract or the load and resource

1 balances of the contract counter party.

2 – Contracted Reserves: These contracts do not take energy. The available
3 capacity is used in the operating reserve calculation.

4 – No-Energy: These contracts are place holders for capturing fixed cost. They
5 do not take energy.

6 In the Pre-dispatch logic, long term firm purchase and sales contracts are
7 dispatched per the specific algorithms designed for their archetype.

8 **Q. Are there any exceptions regarding the procedures just discussed for**
9 **dispatch of short-term firm or long-term firm contracts?**

10 A. Yes. Whether a wholesale contract is identified as long-term firm is entirely
11 based on the length of its term. Consistent with previous treatment, the Company
12 identifies contracts whose term is greater than one year by name. Short-term firm
13 contracts are grouped by delivery point. If a short-term firm contract has
14 flexibility as described for long-term firm contracts, it will be dispatched using
15 the appropriate archetype and listed individually with the long-term contracts.
16 Hourly contract energy dispatch is used in the Dispatch logic to determine the
17 requirements for thermal generation and system balancing transactions.

18 **Reserve requirement in Pre-Dispatch**

19 **Q. Please describe the reserve requirement on the Company's system.**

20 A. The North American Electric Reliability Council (NERC) requires all companies
21 with generation to carry operating reserves to meet its most severe single
22 contingency (MSSC) or 5 percent for operating hydro resources and 7 percent for
23 operating thermal resources, whichever is greater. A minimum of one-half of

1 these reserves must be spinning. Spinning reserves are units that are under
2 control of the control area. The remainder (ready reserves) must be available
3 within a 10-minute period. NERC and the Western Electricity Coordinating
4 Council (WECC) require companies with generation to carry spinning reserves to
5 protect the WECC system from cascading loss of generation or transmission lines,
6 uncontrolled separation and interruption of customer service.

7 **Q. How does the model implement the operating reserve requirement?**

8 A. The model calculates operating reserve requirements (both spinning and ready)
9 for the Company's East and West control areas, plus regulating margin that is
10 added to spinning reserve requirement. The total operating reserve requirement is
11 5 percent of dispatched hydro and 7 percent of committed available thermal
12 resources for the hour, which includes both Company's owned resources and long
13 term firm purchase and sales contracts that contribute to the reserve requirement.
14 Spinning reserve is one half of the total reserve requirement plus regulating
15 margin. Regulating margin is the same in nature as spinning reserve but it is used
16 for following changes in net system load from one hour to the next.

17 **Q. How does the model satisfy reserve requirements?**

18 A. Reserves are met first with unused hydro capability then by backing down thermal
19 units on a descending variable cost basis. Spinning reserve is satisfied before the
20 ready reserve requirement. For each control area, spinning reserve requirement is
21 fulfilled using hydro resources and thermal units that are equipped with governor
22 control. The ready reserve requirement is met using purchase contracts for
23 operating reserves, uncommitted quick start units, the remaining unused hydro

1 capability, and by backing down thermal units. The allocated hourly reserve
2 requirement to the generating units is used in the Dispatch logic to determine the
3 energy available from the resources and the level of the system balancing market
4 transactions.

5 **Q. What is an “uncommitted quick start unit”?**

6 A. As noted above, ready reserves must be available within a 10-minute period. A
7 quick start unit is a unit that can be synchronized with the transmission grid and
8 can be at capacity within the 10-minute requirement. If a gas supply is available
9 and the units are not otherwise dispatched, the Gadsby CT units and the leased
10 West Valley units meet this requirement.

11 **Q. Are the operating reserves for the two control areas independent of each
12 other?**

13 A. Yes, with one exception. The dynamic overlay component of the RTSA
14 agreement with Idaho Power allows the Company to utilize the reserve capability
15 of the Company’s west side hydro system in the east side control area. Up to 100
16 MW of east control area spinning reserves can be met from resources in the west
17 control area.

18 **Q. What is the impact of reserve requirement on resource generating
19 capability?**

20 A. There is no impact on hydro generation, since the amount of reserves allocated to
21 hydro resources are based on the difference between their maximum dependable
22 capability and the dispatched energy. However, if a thermal unit is designated to
23 hold reserves, its hourly generation will be limited to no more than its capability

1 minus the amount of reserves it is holding.

2 **Model Inputs**

3 **Q. Please explain the inputs that go into the model.**

4 A. As mentioned above, inputs used in GRID include retail loads, thermal plant data,
5 hydroelectric generation data, firm wholesale sales, firm wholesale purchases,
6 firm wheeling expenses, system balancing wholesale sales and purchase market
7 data, and transmission constraints.

8 **Q. Please describe the retail load that is used in the model.**

9 A. The retail load represents the forecasted hourly firm retail load that the Company
10 serves within all of its jurisdictions for the twelve-month period ending March 31,
11 2006. The total company load is modeled based on the location of the load and
12 transmission constraints between generation resources to load centers.

13 **Q. Please describe the thermal plant inputs.**

14 A. The amount of energy available from each thermal unit and the unit cost of the
15 energy are needed to calculate net power costs. To determine the amount of
16 energy available, the Company averages for each unit, four years of historical
17 outage rates and maintenance. The heat rate for each unit is determined by using
18 a four-year average of historical burn rate data. By using four-year averages to
19 calculate outages, maintenance and heat rate data, annual fluctuations in unit
20 operation and performance are smoothed. The four-year period used by the
21 Company in this filing is the 48-month period ending March 2004. Other thermal
22 plant data includes unit capacity, minimum generation level, minimum up/down
23 time, fuel cost, and startup cost. The Company's use of a four-year average was

1 previously adopted by the Utah Commission.

2 **Q. Please describe the hydroelectric generation input data.**

3 A. As stated earlier, the Company has a new source for its hydro data. The Company
4 is using 19 sets of expected generation from the VISTA hydro model rather than
5 using the 50 years of adjusted actual stream flows.

6 **Q. Does using the VISTA model cause an increase in NPC?**

7 A. No. Net power costs are lower as a result of adopting the Vista model. However,
8 the new licensing requirements for the Umpqua River projects which was
9 partially effective September 2003 with the remainder effective January 1, 2006
10 and the new Grant County contract which is effective November 2005 offset most
11 of the NPC decrease.

12 **Q. Please describe the changes in the new Umpqua license and the new Grant
13 County contract that increase NPC.**

14 A. For the Umpqua River, effective 2001, the Soda plant has been operated more like
15 a re-reg facility than in the past – by smoothing out the flow and following a 5
16 percent change per 24 hour rule. In September 2003, the minimum fish flow
17 below Soda was increased from 25 to 95 cubic feet per second. Additional
18 minimum flow requirements phase in over time. By January 1, 2006, all of the
19 minimum by pass flows will be in operation. By 2006, the estimate impact of
20 these changes is a loss of 125,000 MWh per year.

21 The Priest Rapids Project consists of the Priest Rapids Development and
22 the Wanapum Development. Two contracts with Grant tied to the Priest Rapids
23 Project. Each of the contracts allocates a percentage of the firm energy and

1 capacity of the development, plus the same percentage of non-firm energy from
2 the development to the Company. The contract for the Priest Rapids
3 Development (13.9 percent) expires October 31 2005. The contract for the
4 Wanapum Development (18.7 percent) expires October 31 2009. The two
5 contracts are succeed by a set of contracts related to Priest Rapids Project. They
6 are:

- 7 • Priest Rapids Product Sale Contract
- 8 • Priest Rapids Reasonable Portion Power Sales Contract
- 9 • Additional Products Sales Agreement

10 The Product Sale contract allocates the Company a percentage of the project that
11 is surplus to Grant's needs (Surplus Product). The percentage includes firm
12 energy and capacity of the project, plus the same percentage of non-firm energy
13 from the project. This contract also allocates the Company a percentage of the
14 energy that becomes available when Grant buys displacement energy from BPA
15 (Displacement Product). The Additional Products Sales Agreement gives the
16 Company a percentage of Grant's non-firm energy from the project. In the test
17 period the Company estimates the new contracts will result in approximately a
18 95,000 MWH reduction in energy compared to the prior contract. The
19 Reasonable Portion Power Sales contract gives the Company a percentage of the
20 net proceeds from selling the Reasonable Portion of the contract. The Reasonable
21 Portion is the 30 percent of the Project that must be sold in the market place.

22 **Q. Please describe the VISTA model.**

23 A. The Company uses the VISTA Decision Support System (DSS) developed by

1 Synexus Global of Niagara Falls, Canada as its hydro optimization model. The
2 VISTA model is designed to maximize the value of the hydroelectric resources by
3 optimizing the operation of hydroelectric facilities against a projected stream of
4 market prices. VISTA uses an hourly linear program to define the system
5 configuration and the environmental, political, and biological requirements for
6 that system. The physical project data, constraint description, and historical
7 stream flows used in the VISTA model in the preparation of hydro generation
8 proposed for use in this filing are exactly the same data used by the Company's
9 Operations Planning Group and in the Company's Integrated Resource Planning
10 process. The VISTA DSS model is used by a growing number of other energy
11 companies including the Bonneville Power Administration.

12 **Q. Please describe the VISTA model's output.**

13 A. The VISTA model calculates the probability of achieving a level of generation,
14 the model output is expressed in terms of "exceedence" levels. Each exceedence
15 level represents the probability of generation exceeding a given level of
16 generation. These probabilities can also be thought of as percentiles. The
17 Company is using 19 sets of expected generation from the VISTA model rather
18 than using the 50 water years of adjusted actual previously employed. The 19 sets
19 of generation consist of the 5th percentile through the 95th percentile in
20 increments of 5 percent. The wettest year is the 5th percentile and the 95th
21 percentile is the driest. The future projected net power costs are the average of
22 the 19 net power cost studies using the 19 "percentile" sets of hydro generation.

1 **Q. Why is the Company changing to the VISTA model?**

2 A. As far back as the mid-1970's, PacifiCorp and other utilities in the Northwest
3 have used regional historical stream flow records provided by the Bonneville
4 Power Administration (BPA) to normalize expected hydro generation. BPA
5 adjusted the historical stream flow data for changes in the river system (e.g. new
6 projects), the license requirements (e.g. fish flush), and the environment (e.g.
7 more surface runoff). The Company started with 40 years of adjusted historical
8 data (water-years 1929 to 1968). In the mid-1980's BPA added a block of ten
9 years to the adjusted numbers.

10 In the 1990's, when BPA was mandated to be more competitive, BPA
11 stopped sharing and/or preparing the regional information. The only information
12 available was the data made public during the BPA rate case process. Without
13 BPA maintaining the regional hydro information, the hydro data used in prior
14 general rate cases is growing stale.

15 For company-owned projects, the Company has been using the 50 water-
16 year set of hydro generation based on a BPA West Group Forecast Regulation
17 (circa 1986). For the Mid-Columbia projects, the Company has been using data
18 from the 1999 BPA White Book generation forecast for water-years 1929 to 1978.

19 In 2003, the Company started using hydro generation developed by the
20 VISTA model in its Integrated Resource Plan (IRP). Starting in spring 2004, the
21 Company is using the VISTA model to develop hydro generation for its short
22 term planning.

23 Based on the need for more current hydro information and the Company's

1 experience with the VISTA model, the Company decided to use the VISTA
2 model in general rate cases.

3 **Q. Please describe the VISTA model inputs.**

4 A. The VISTA input data comes from a variety of sources characterized into three
5 groups – Company-owned plants without operable storage, Company-owned
6 plants with operable storage, and Mid-Columbia contracts. The Company owns a
7 large number of small hydroelectric plants scattered across its system. These
8 projects have no appreciable storage ponds and are operated as Run-of-River
9 projects; i.e., flow in equals flow out. For these plants “normalized generation” is
10 based on a statistical evaluation of historical generation adjusted only for
11 scheduled maintenance. The results are defined as exceedence level statistics for
12 each hour. The hourly data has been aggregated to the monthly level for use in
13 GRID. The Company’s larger projects (Lewis River, Klamath River, and
14 Umpqua River) have a range of possible generation that can be modified
15 operationally by effective use of storage reservoirs. For these projects, the
16 Company feeds the historical stream-flow data through its optimization model,
17 VISTA, to create a set of generation possibilities that reflect the current capability
18 of the physical plant, the operating requirements of the current license
19 agreements, as well as the current energy market price projections.

20 For the Lewis and Klamath Rivers, the stream flows used as inputs to the
21 VISTA model are the flows that have been recorded by the Company at each of
22 the projects. In most cases the flows, using a very simple continuity of water
23 equation where $\text{Inflow} = \text{Outflow} + \text{Change in Storage}$, are used to develop

1 generation levels.

2 For the Umpqua River, the inflow data was reconstructed by piecing
3 together a variety of historical data sources. The USGS gauge data at Copeland
4 (the outflow of the entire project) was used to true up the previously recorded
5 flows developed using the continuity equation described above.

6 The Company's Mid-Columbia energy is determined by using VISTA to
7 optimize the operations of the of the six hydro electric facilities below Chief
8 Joseph under 60 years of "modified" stream-flow conditions. The modified hydro
9 flows are the flows developed as the "PNCA Headwater Payments Regulation
10 2002" file, also known as "The 2002 60 year Reg" file, completed in February
11 2003 for hydro conditions that actually occurred for the period 1928 through
12 1988. Thus the inflows to the Mid-Columbia projects are the result of extensive
13 modeling that reflects the current operations and constraints of the Columbia
14 River. This stream flow data is the most current information available to the
15 Company and serves as an input to the VISTA model. As in the case of the
16 Company's large plants the energy production resulting from the set of stream
17 flows is analyzed statistically to produce a set of probability curves or exceedence
18 levels for each hour/day.

19 **Q. In previous Utah cases, hydroelectric generation was normalized by using**
20 **historical water data. Is that still true with the VISTA model?**

21 A. Yes. The period of historical data varies by plant. As noted above, the Mid-
22 Columbia projects are adjusted to water year 1928/29. The Company's large
23 plant data begins in the 1958-1963 range. The Company's small plant data begins

1 in the 1978-1989 range.

2 **Q. Is the input of hydro generation located outside of the Northwest modeled in**
3 **the same manner as the Pacific Northwest hydro generation?**

4 A. Yes. Using the VISTA model, the input of hydro generation located in Utah and
5 Southeast Idaho are now calculated in the same manner as the Pacific Northwest
6 hydro generation.

7 **Q. Does the Company use other hydro generation inputs?**

8 A. Yes. Other parameters for the hydro generation logic include the maximum
9 capability, the minimum run requirements, shaping capability, and reserve
10 carrying capability of the projects.

11 **Q. Please describe the input data for firm wholesale sales and purchases.**

12 A. The data for firm wholesale sales and purchases are based on contracts to which
13 the Company is a party. Each contract specifies the basis of quantity and price.
14 The contract may specify an exact quantity of capacity and energy or a range
15 bounded by a maximum and minimum amount, or it may be based on the actual
16 operation of a specific facility. Prices may also be specifically stated, may refer
17 to a rate schedule, a market index such as California Oregon Border (COB), Mid
18 Columbia (Mid C) or Palo Verde (PV), or may be based on some type of formula.
19 The long-term firm contracts are modeled individually, and the short-term firm
20 contracts are grouped based on general delivery points. The long-term contracts
21 are dispatched against the hourly market prices so that they are optimized from
22 the point of view of the holder of the call/put.

1 **Q. Please describe the input data for wheeling expenses and transmission**
2 **capability.**

3 A. The data for firm wheeling is based on contracts to which the Company is a party.
4 The firm transmission rights modeled in GRID are developed from the
5 Company's OASIS for summer/winter postings. The limited additional
6 transmission rights that the Company may have access to are based on the
7 experience of the Company's Commercial and Trading Department.

8 **Q. Please describe the system balancing wholesale sales and purchase input**
9 **assumptions.**

10 A. The GRID model uses four wholesale markets to balance and optimize the
11 system. The four markets are at Mid Columbia, COB, SP15 and Palo Verde
12 (Desert Southwest), where the model makes both system balancing sales and
13 purchases if it is economical to do so under constraints. The input data regarding
14 wholesale markets include market price and market size.

15 **Q. What market prices are used in the net power cost calculation?**

16 A. The market prices for the system balancing wholesale sales and purchases at Mid
17 Columbia, COB, SP15 and Palo Verde (DSW) are the Company's monthly
18 forward price curves for the period April 2005 through March 2006 shaped into
19 hourly prices. The market price hourly scalars are developed by the Company's
20 Commercial and Trading Department based on historical hourly data since April
21 1996. Separate scalars are developed for on-peak and off-peak periods and for
22 different market hubs to correspond to the categories of the monthly forward
23 prices. Before the determination of the scalar, the historical hourly data are

1 adjusted to synchronize the weekdays, weekends and holidays, and to remove
2 extreme high and low historical prices. As such, the scalars represent the
3 expected relative hourly price to the average price forecast for a month. The
4 hourly prices for the test period are then calculated as the product of the scalar for
5 the hour and the corresponding monthly price.

6 **Normalization**

7 **Q. Please explain what is meant by normalization and how it applies to the**
8 **production cost model for future test years.**

9 A. For future test years, normalization of input data for the production cost model is
10 primarily limited to hydro data. Owned and purchased hydroelectric generation is
11 normalized by running the production cost model for each of the 19 different sets
12 of hydro generation. The resultant 19 sets of thermal generation, system
13 balancing sales and purchases, and hydroelectric generation are then averaged.
14 As previously explained, normalized thermal availability is based on a four-year
15 average adjusted to remove the Hunter 1 extraordinary outage.

16 **Q. You stated that hydroelectric generation is normalized by using historical**
17 **water data. Please explain why the regulatory Commissions and the utilities**
18 **of the Pacific Northwest have adopted the use of production cost studies that**
19 **employ historical water conditions for normalization.**

20 A. In any hydroelectric-oriented utility system, water supply is one of the major
21 variables affecting power supply. The operation of the thermal electric resources
22 both within and outside the Pacific Northwest are directly affected by water
23 conditions within the Pacific Northwest. During periods when the stream flows

1 are at their lowest, it is necessary for utilities to operate their thermal electric
2 resources at a higher level or purchase more from the market, thereby
3 experiencing relatively high operating expenses. Conversely, under conditions of
4 high stream flows, excess hydroelectric production may be used to reduce
5 generation at the more expensive thermal electric plants, which in turn results in
6 lower operating expenses for some utilities and an increase in the revenues of
7 other utilities, or any combination thereof. No one water condition can be used to
8 simulate all the variables that are met under normal operating conditions. Utilities
9 and regulatory commissions, therefore, have adopted production cost analysis that
10 simulates the operation of the entire system using historical water conditions, as
11 being representative of what can reasonably be expected to occur.

12 **Model Outputs**

13 **Q. What variables are calculated from the production cost study?**

14 A. These variables are:

- 15 – Dispatch of firm wholesale sales and purchase contracts;
- 16 – Dispatch of hydroelectric generation;
- 17 – Reserve requirement, both spinning and non-spinning;
- 18 – Allocation of reserve requirement to generating units;
- 19 – The amount of thermal generation required; and
- 20 – System balancing wholesale sales and purchases.

21 **Q. What reports does the study produce using the GRID model?**

22 A. The major output from the GRID model is the Net Power Cost report. Additional
23 data for more detailed analyses is also available whose format can be hourly,

1 daily, monthly, annually and by heavy load hours and light load hours.

2 **Q. Do you believe that the GRID model appropriately reflects the Company's**
3 **operating relationship in the environment that it operates in?**

4 A. Yes. The GRID model appropriately simulates the operation of the Company's
5 system over a variety of streamflow conditions consistent with the Company's
6 operation of the system including operating constraints and requirements.

7 **Q. Please describe Exhibit UP&L____(MTW-1).**

8 A. This Exhibit is a schedule of the Company's major sources of energy supply by
9 major source of supply, expressed in average megawatts owned and contracted for
10 by the Company to meet system load requirements, for the test period. The total
11 shown on line 11 represents the total future usage of resources during the test
12 period to serve system load. Line 12 consists of wholesales sales made to
13 neighboring utilities within the Pacific Northwest, the Pacific Southwest, and the
14 Desert Southwest as calculated from the production cost model study. Line 13
15 represents the Company's System Load net of special sales.

16 **Q. Please describe Exhibit UP&L____(MTW-2).**

17 A. This Exhibit lists the major sources of future peak generation capability for the
18 Company's winter and summer peak loads and the Company's energy load for the
19 test period.

20 **Aquila Hydro Hedge**

21 **Q. Please explain your recommendation for the Aquila Hydro Hedge payment**
22 **received by the Company.**

23 A. In order to mitigate the negative effects of annual fluctuations of hydro conditions

1 upon net power costs, the Company has entered into a contract (the “Aquila
2 Hydro Hedge”) with Aquila Risk Management Corporation (“Aquila”) that
3 provides financial protection when stream flow levels are low. The financial
4 contract is structured as a collar, whereby PacifiCorp makes a payment to Aquila
5 if stream flows are above a certain level (when power prices would tend to be
6 low), and Aquila makes a payment to PacifiCorp if stream flows are below a
7 certain level (when power prices would tend to be high). The Aquila Hydro
8 Hedge is measured on a quarterly and October to September contract year basis.
9 Any payments will be made on a quarterly basis based on actual stream flows for
10 that quarter. Any payments made or received are held on the Company’s balance
11 sheet until a final determination for the contract year. I believe these revenues
12 and costs should be returned to customers through a balancing account. The
13 balancing account treatment will be discussed in Mr. Griffith’s testimony.

14 **Q. Does this conclude your direct testimony?**

15 A. Yes.
