## TABLE OF EXHIBITS

CSS Exhibit (PLC-8D.1)	<i>Professional Qualifications of Paul Chernick</i>
CSS Exhibit (PLC-8D.2)	<i>The Effect of Energy Use in High-Load Periods on the Cost and Sizing of Transformers</i>

1 **I. Identification and Qualifications**

2 **Q: Mr. Chernick, please state your name, occupation and business address.**

3 A: I am Paul L. Chernick. I am the president of Resource Insight, Inc., 5 Water  
4 Street, Arlington, Massachusetts.

5 **Q: Summarize your professional education and experience.**

6 A: I received an SB degree from the Massachusetts Institute of Technology in June  
7 1974 from the Civil Engineering Department, and an SM degree from the  
8 Massachusetts Institute of Technology in February 1978 in technology and  
9 policy. I have been elected to membership in the civil engineering honorary  
10 society Chi Epsilon, and the engineering honor society Tau Beta Pi, and to  
11 associate membership in the research honorary society Sigma Xi.

12 I was a utility analyst for the Massachusetts Attorney General for more  
13 than three years, and was involved in numerous aspects of utility rate design,  
14 costing, load forecasting, and the evaluation of power supply options. Since  
15 1981, I have been a consultant in utility regulation and planning, first as a  
16 research associate at Analysis and Inference, after 1986 as president of PLC,  
17 Inc., and in my current position at Resource Insight. In these capacities, I have  
18 advised a variety of clients on utility matters.

19 My work has considered, among other things, the cost-effectiveness of  
20 prospective new generation plants and transmission lines, retrospective review  
21 of generation-planning decisions, ratemaking for plant under construction,  
22 ratemaking for excess and/or uneconomical plant entering service, conservation  
23 program design, cost recovery for utility efficiency programs, the valuation of  
24 environmental externalities from energy production and use, allocation of costs  
25 of service between rate classes and jurisdictions, design of retail and wholesale

26 rates, and performance-based ratemaking and cost recovery in restructured gas  
27 and electric industries. My professional qualifications are further described in  
28 CSS Exhibit (PLC-8D.1).

29 **Q: Have you testified previously in utility proceedings?**

30 A: Yes. I have testified approximately one hundred and ninety times on utility  
31 issues before various regulatory, legislative, and judicial bodies, including the  
32 Arizona Commerce Commission, Connecticut Department of Public Utility  
33 Control, District of Columbia Public Service Commission, Florida Public  
34 Service Commission, Maryland Public Service Commission, Massachusetts  
35 Department of Public Utilities, Massachusetts Energy Facilities Siting Council,  
36 Michigan Public Service Commission, Minnesota Public Utilities Commission,  
37 Mississippi Public Service Commission, New Mexico Public Service Commis-  
38 sion, New Orleans City Council, New York Public Service Commission, North  
39 Carolina Utilities Commission, Public Utilities Commission of Ohio, Pennsyl-  
40 vania Public Utilities Commission, Rhode Island Public Utilities Commission,  
41 South Carolina Public Service Commission, Texas Public Utilities Commission,  
42 Utah Public Service Commission, Vermont Public Service Board, Washington  
43 Utilities and Transportation Commission, West Virginia Public Service Commis-  
44 sion, Federal Energy Regulatory Commission, and the Atomic Safety and  
45 Licensing Board of the U.S. Nuclear Regulatory Commission.

46 **Q: Have you testified previously before the Commission?**

47 A: Yes. I testified on behalf of the Utah Committee of Consumer Services (“the  
48 Committee”) in the following dockets:

- 49 • Docket No. 98-2035-04, on the proposed acquisition of PacifiCorp by  
50 Scottish Power. My testimony addressed proposed performance standards  
51 and valuation of performance.

52 • Docket No. 99-2035-03, on the sale of the Centralia coal plant. My  
53 testimony addressed the costs of replacement power, the allocation of plant  
54 sale proceeds, and the potential rate impacts on Utah customers of  
55 PacifiCorp’s decision to sell the plant. I testified that the sale of Centralia  
56 was not in the interest of ratepayers and that if the Commission approved  
57 the sale it should allocate more of the sale proceeds to Utah to mitigate  
58 potentially high replacement power costs. The Commission adopted this  
59 latter recommendation as part of approving the sale.

60 I also assisted the Committee in analyzing various issues in the multi-state  
61 process. These issues included resource planning, cost allocation of generation-  
62 and-transmission plant, regulatory policy and risk analysis.

## 63 **II. Introduction**

64 **Q: On whose behalf are you testifying in this rate case proceeding?**

65 A: My testimony is sponsored by the Committee.

66 **Q: What issues does your testimony address?**

67 A: I evaluate the following proposals of Rocky Mountain Power (“RMP” or “the  
68 Company”):

- 69 • The classification and allocation factors in the Cost of Service Study  
70 (“COS Study”);
- 71 • The irrigator-load-research study;
- 72 • The Company’s reliance on its Cost of Service Study as the basis for its  
73 class rate spread proposal;
- 74 • Proposed rate design changes to Residential Schedule 1, in particular the  
75 introduction of the Customer Load Charge (“CLC”) for usage over 1000  
76 kWh in the summer months.

77 **Q: Prior to hearings on the revenue-requirement phase of the case in early**  
78 **June 2008, RMP reduced its rate request from approximately \$99 million**  
79 **(7.5%) to \$74.5 million (5.6%) (excluding special contract customers). What**  
80 **COS Study and proposed rate schedules do you address?**

81 A: I evaluated the COS Study and proposed rate schedules presented in Exhibits  
82 RMP\_\_(CCP-3S) and RMP\_\_(WRG-1S through 4S), which are both linked to  
83 the 7.5% rate increase request. The Company did not update its proposed rate  
84 schedules to comport with its lower 5.6% revenue requirement request.

### 85 **III. Evaluation of RMP's Cost-of-Service Study**

86 **Q: What is the purpose of the cost-allocation process?**

87 A: The purpose of the cost-allocation process is the fair assignment of the total  
88 Utah jurisdictional revenue requirement to the various tariffed rate classes.<sup>1</sup> A  
89 fundamental principle of the process is that allocation based on cost causation  
90 results in an equitable sharing of embedded costs. As Company Witness William  
91 Griffith explains in his Direct Testimony (at 3), the COS Study process  
92 “recognize[s] the way a utility provides electrical service and assigns cost  
93 responsibility to the groups of customers for whom those costs were incurred.”

94 **Q: What role should the embedded COS Study play in revenue allocation?**

95 A: Any embedded-cost-based COS Study is approximate and based on judgment.  
96 Therefore, it should serve only as a guide to class rate spread.

97 **Q: Should the COS Study be the basis of rate design as well as rate spread?**

---

<sup>1</sup>There are also cost-allocation implications for certain special contract customers due to escalation clauses in their respective contracts.

98 A: No. Considerations of marginal cost and incentive effects, not embedded cost,  
99 should be the primary basis for design of rates for individual classes.

100 **Q: Should the Commission expect allocation methods to change over time?**

101 A: Yes. The COS Study methodology should not be fixed in stone. It should be  
102 updated or revised as needed to address changes in any of the following:

- 103 • the conceptual models of cost causation;
- 104 • data availability;
- 105 • the environment in which utilities operate, such as the structure of whole-  
106 sale markets and cost patterns;
- 107 • energy and regulatory policy.

108 **A. *Reasonableness of Classification and Allocation Factors***

109 **Q: Does RMP's COS Study reasonably reflect cost causation?**

110 A: No. I have identified a number of problems with the Company's classification  
111 and allocation decisions that are likely to overstate the net costs incurred to  
112 serve the residential, small commercial and irrigation classes. In particular,  
113 RMP's COS Study

- 114 • understates the energy-related costs of generation, especially coal and wind  
115 resources;
- 116 • understates the energy-related portion of firm power purchase costs;
- 117 • almost certainly understates the energy-related costs of transmission;
- 118 • misallocates monthly off-system firm sales revenues to rate classes, in that  
119 the Study ignores individual class contributions to supporting the resources  
120 from which off-system sales are made and the extent to which class loads  
121 allow PacifiCorp to make those sales;
- 122 • minimizes the effects of energy use on distribution costs;

- 123       • ignores the sharing of service drops by residential customers in multi-  
124           family dwellings.

125    1.   *The Classification of Generation Plant*

126    **Q: How is generation plant classified?**

127    A:   The COS Study classifies “seasonal” generation plant (including combustion  
128       turbines) as 100% demand-related and baseload and intermediate generation  
129       plant as 75% demand-related and 25% energy-related. This approach recognizes  
130       that power production facilities are built both to serve demand (i.e., to meet  
131       reliability requirements) and to produce energy economically.

132    **Q: How did PacifiCorp come to use the 75-25 demand-energy classification  
133       split for generation?**

134    A:   As I understand the history of this classification split, 75-25 split was initially a  
135       compromise between the Pacific Power and Light’s 50-50 classification and the  
136       Utah Power and Light’s 100% demand classification, in place at the time of the  
137       PacifiCorp merger. I also understand that PacifiCorp analyzed the demand-  
138       energy classification in the early 1990s, as part of the work performed within the  
139       PacifiCorp Interjurisdictional Task Force on Allocations process. However, the  
140       Utah Commission never ruled on the classification issue until its rate case  
141       decision in Docket No. 97-035-01.

142    **Q: What did the Commission decide in that rate case proceeding?**

143    A:   Acknowledging that energy needs are a significant driver of generation capital  
144       costs, the Commission adopted the Division’s qualitative argument in support of  
145       a 75-25 demand-energy classification:

146 Citing both past operating experience and future resource planning, the  
147 Division notes that resources with higher energy availability are chose over  
148 those with lower energy availability. Since energy plays a role in the  
149 selection of least-cost resources, the Division concludes that some weight  
150 needs to be given to energy in planning for new capacity, and the current  
151 weight of 25 percent is reasonable. We find the *qualitative argument*  
152 offered by the Division to be...convincing. (PSC Order, Docket No. 97-  
153 035-01 at 82, emphasis added)

154 **Q: From a quantitative standpoint, how can the energy-related portion of**  
155 **generation plant costs be estimated?**

156 A: One approach is the *peaker method*, which considers the demand-related portion  
157 of production plant to be the minimum cost of providing the current system  
158 reliability level, and the remainder to be the energy-related portion. The  
159 Company previously endorsed this concept in the 1989 UP&L Distribution  
160 Study at 11:

161 The increased cost of a baseload unit over a peaking plant represents an  
162 investment made to save fuel costs. The additional investment can be  
163 classified as energy related.... The generation plants have two equally  
164 important ratings, energy and demand.

165 **Q: Is the peaker approach consistent with the current electricity markets?**

166 A: Yes. The Independent System Operators (“ISOs”) for restructured markets apply  
167 a pricing model similar to the peaker method, which are even more weighted to  
168 energy. For example,

- 169 • The New York ISO and PJM determine the price of capacity from a form-  
170 ula that sets the capacity price near the cost of a peaking unit, net of energy  
171 revenues, when installed capacity is close to the required level.
- 172 • The New England ISO sets capacity prices through a forward auction. The  
173 initial starting price for the auction, as well as minimum and maximum  
174 prices, are determined by the cost of a new peaker, net of energy revenues.

175 • Other ISOs, including the California ISO, Midwest ISO, and ERCOT, have  
176 no installed capacity requirements at all, and charge load primarily on  
177 time-of-use energy consumption.

178 **Q: Please explain how the peaker method would be used to classify generation**  
179 **plant in a COS Study.**

180 A: For each generation unit, a good initial estimate of the demand- or reliability-  
181 related portion of its cost is the cost per kW of a contemporaneous peaker  
182 (generally a simple-cycle combustion turbine) times the rated capacity of the  
183 unit. The cost of the unit in excess of the equivalent gas turbine capacity is  
184 energy-related.<sup>2</sup>

185 **Q: Have you applied the peaker method to PacifiCorp's existing coal plants?**

186 A: Yes. Figure 1, below, shows the gross capital cost per kilowatt at the end of  
187 2006, for each existing PacifiCorp coal plant and for the combustion-turbine  
188 plants, sorted by in-service date.<sup>3</sup> The peakers averaged under \$200/kW,  
189 compared to \$500–\$1,000/kW for the PacifiCorp coal plants, suggesting that  
190 60% to 80% of the coal plant capital costs are energy-related.

---

<sup>2</sup>This calculation overstates the reliability-related portion of plant cost: it assumes steam plant supports as much firm demand as would be supported by the same capacity of combustion turbines. Higher forced outage rates, large maintenance requirements, and the size of large units all tend to reduce the contribution of large units to system reliability.

<sup>3</sup>The peakers are those owned by investor-owned utilities in Arizona, Colorado, Montana, New Mexico, Nevada, Oregon, and Washington, and were all built during the period 1970–1981. PacifiCorp does not own any peakers built in the same period as its coal plants.

204 megawatt of installed wind capacity, the fixed costs of wind are about 95%  
205 energy-related.<sup>4</sup>

206 **Q: Would changing the demand-energy classification split for PacifiCorp’s**  
207 **generation plant have a significant effect on the cost allocation?**

208 A: Yes. Just changing RMP’s Factor 10 (the demand-allocated portion of fixed  
209 plant costs) from 75% to 50% shifts about \$8.5 million off of Schedules 1, 6,  
210 and 23, and about \$3.8 million onto Schedules 8 and 9.<sup>5</sup>

211 **Table 1**

<b>Schedule</b>	<b>Change in Allocation (Million \$)</b>
1	-2.4
6	-4.3
8	0.4
9	3.4
23	-1.8

212 The demand-related portion of PacifiCorp owned generation, weighted  
213 across PacifiCorp’s generation mix, may be much lower than 50%, so the effects  
214 may be much larger.

215 2. *Allocation of Firm Non-Seasonal Purchases*

216 **Q: How does RMP allocate firm non-seasonal purchases?**

---

<sup>4</sup>The costs of PacifiCorp’s new wind plants, and of the Gadsby peakers, are very similar to the assumptions in the IRP.

<sup>5</sup>This example, and the other examples I present of allocation effects, are based on RMP’s 8.19% target return. In addition to the impacts on the major tariffed classes, reducing Factor 10 to 50% would increase the allocation to special contract customers. Regarding subsequent changes in “Factors,” the allocation impacts for special contract customers is in the same directions as that in Schedule 9.

217 A: The Company classifies firm non-seasonal purchases as 75% demand-related  
 218 and 25% energy-related and allocates each month's cost separately based on  
 219 class coincident peak and kWh usage in that month.

220 **Q: Has the energy-related portion of firm non-seasonal purchase costs been**  
 221 **understated?**

222 A: Yes, in two important ways. First, the non-seasonal purchases are likely to  
 223 reflect RMP's mix of non-seasonal generation plant, which are more energy-  
 224 related than the COS Study assumes, as discussed above in Section III.A.1.

225 Second, RMP allocates purchases and generation inconsistently. In the case  
 226 of its own generation plant, RMP treats fuel costs and plant costs separately, and  
 227 classifies fuel as 100% energy-related, and plant as 75% demand/25% energy-  
 228 related. But in the case of firm non-seasonal purchases, RMP does not attempt to  
 229 separate the variable and fixed components and instead treats all purchases costs  
 230 as fixed plant costs. As a result, RMP allocates only 25% of all purchase costs,  
 231 including fuel costs, on energy. This difference is illustrated in the table below:

232 **Table 2**

Percent Allocated on Energy		
<i>F</i>	<i>F</i>	<i>T</i>
<i>i</i>	<i>u</i>	<i>o</i>
<i>x</i>	<i>e</i>	<i>t</i>

<i>o</i>	<i>d</i>	<i>f</i>
<i>s</i>	<i>V</i>	<i>H</i>
<i>t</i>	<i>a</i>	<i>a</i>
<i>s</i>	<i>r</i>	<i>l</i>
	<i>i</i>	<i>f</i>
	<i>a</i>	
	<i>b</i>	
	<i>l</i>	<i>o</i>
	<i>e</i>	<i>f</i>
	<i>C</i>	<i>C</i>
	<i>o</i>	<i>o</i>
	<i>s</i>	<i>s</i>
	<i>t</i>	<i>t</i>

	S		I S F u e l
P l a n t	2 5 %	1 0 0 %	6 2 .5 %
N o n - S e a s o n a l P u r c h a s e s	2 5 %	2 5 %	2 5 %

233 **Q: How significant is the disparity between RMP's classification of purchases**  
 234 **and generation?**

235 A: The disparity is quite large. From the 2007 PacifiCorp IRP, I computed the  
 236 portion of total costs that RMP would allocate on energy for each potential new  
 237 resource. The energy-related portion of the costs is the sum of variable costs  
 238 plus 25% of fixed costs for non-seasonal resource, and just variable costs for  
 239 peakers. The portion of generator costs allocated on energy under RMP's current  
 240 classification and allocation method ranges from 46% for Wyoming IGCC to

241 61% for Utah pulverized coal, 55% to 76% for various types of combustion  
 242 turbines, and 76%–83% for various combined-cycle configurations.

243 **Figure 2: Energy-Related Share of New Resource Costs in RMP’s COS Study**

244 **Q: Would changing the demand-energy classification split for firm non-**  
 245 **seasonal purchases have a significant effect on the cost allocation?**

246 **A:** Yes. Changing RMP’s Factor 87 (the demand-allocated portion of firm non-  
 247 seasonal purchases) from 75% to 25% shifts about \$13 million off of Schedules  
 248 1, 6, and 23, and about \$5.5 million onto Schedules 8 and 9.

249 **Table 3**

<b>Schedule</b>	<b>Change in Allocation (Million \$)</b>
1	-2.4
6	-8.0
8	0.3
9	5.2
23	-2.5

250 3. *The Allocation of Firm Sales Revenue*

251 **Q: How does RMP allocate firm sales revenue?**

252 A: As with firm non-seasonal purchases, RMP classifies firm sales as 75% demand-  
253 related and 25% energy-related. The monthly allocation factors for sales and  
254 purchases are the same.<sup>6</sup>

255 **Q: Why is this allocation approach inappropriate?**

256 A: Under this allocator, the greater the rate class's demand and usage during a  
257 month, the greater its share of the months' firm sales revenue. The correct allo-  
258 cator would reward a class for having lower demand and usage in the month,  
259 thereby leaving generation (and transmission) capacity available to support the  
260 off-system sales.<sup>7</sup>

261 **Q: Can you provide an example of the misallocation of firm sales revenues?**

262 A: Yes. The irrigation class is assigned 0.761% of (non-seasonal) production plant,  
263 0.627% of firm non-seasonal purchases and 1.519% of firm seasonal purchases,  
264 but receives only 0.58% of the firm sales revenues.

265 **Q: Why are the allocations of costs and revenues so skewed in the case of the  
266 irrigation class?**

267 A: In the test year, 96% of irrigation kWh usage occurs in the higher-cost summer  
268 months (May–September), but only 35% of the firm sales revenues are made in  
269 those months (Excel file COS UT Dec 2008 (MSP).xls, Tabs “Energy Factor”  
270 and “NPC Factors”). In the non-summer months, when irrigation kWh use is

---

<sup>6</sup>The annual allocation factors differ in part because sales and purchases do not follow the same monthly pattern.

<sup>7</sup>The allocator must also recognize that purchases in the current month may also contribute to serving the off-system sales that month.

271 negligible, firm sales revenue is high; in particular, average sales in January  
272 through March exceed the summer average by 64%.

273 The irrigation class should receive a credit for making its share of capacity  
274 available for off-system sales in the winter months.

275 **Q: Have you been able to determine the effect on the class allocation of an**  
276 **improved allocator for firm off-system firm sales?**

277 A: No. The COS Study is not designed to allow a user to change the allocation of  
278 sales revenues among months. Furthermore, several factors should be reflected  
279 in the allocation of sales revenues, and those should vary with the type of sale  
280 (e.g., off-peak, around-the-clock, peak hours).

281 **Q: Can you give the Commission a sense of the potential effect of a more**  
282 **appropriate allocation of off-system firm sales revenue?**

283 A. Yes. I computed three additional sales allocators. The first allocates monthly  
284 sales revenues, in excess of July and August sales, in proportion to the difference  
285 between the class's contribution to annual coincident peak and the class's  
286 contribution to monthly coincident peak. The second allocator allocates each  
287 month's sales revenue in proportion to the class's unused energy in that month:  
288 its contribution to potential energy (annual coincident peak times the hours in  
289 the month) minus the class's energy use in the month. The third allocator is the  
290 same as the second, except that the potential energy is increased by a 15%  
291 reserve margin. The class results are as follows:

292

**Table 4**

		RMP Allocation	Unused Energy Compared to Peak		Unused CP Sales > Summer
			<i>peak + 15%</i>	<i>peak</i>	
Residential	Sch 1	30.54%	57.98%	64.84%	91.59%
GS Dist—Large	Sch 6	29.23%	24.34%	23.83%	4.00%
GS Dist—> 1MW	Sch 8	9.18%	6.02%	5.28%	3.43%
GS Trans	Sch 9	17.60%	4.57%	0.97%	-6.17%
Irrigation	Sch 10	0.58%	2.53%	2.91%	6.89%
GS Dist—Small	Sch 23	6.62%	9.19%	10.11%	8.88%

293

A fully developed allocator for off-system firm sales revenue would probably fall somewhere between RMP’s allocator and those I developed. Such an allocator would increase allocation of off-system sales revenue to Schedules 1, 23, and, especially, 10, and decrease sale revenue allocations to Schedules 6, 8, and 9.

294

295 **Q: Could these changes be significant?**

296 A: Yes. RMP estimates \$590 million in off-system sales revenues, so every 1%  
 297 shift is worth \$5.9 million.<sup>8</sup> A \$5.9 million change in cost allocation would  
 298 change the revenue allocated to Schedules 1, 6, and 9 by about 1%–3%;  
 299 Schedules 8 and 23 by about 5%; and Schedule 10 by about 45%. In addition to  
 300 the concerns with the irrigator load data discussed later in my testimony, the  
 301 Commission should note that a small change in the off-system-sales revenue  
 302 allocation could eliminate the revenue shortfall RMP reports for irrigation. The  
 303 effects on other classes could also be material.

304 **4. The Classification of Transmission Plant**

305 **Q: How does the COS Study classify transmission plant?**

---

<sup>8</sup>There may be indirect allocation effects as well.

309 A: It classifies 75% of transmission costs as demand-related and 25% as energy-  
310 related. This classification recognizes that, while peak loads are a major driver  
311 of transmission costs, a significant portion of transmission costs are incurred to  
312 reduce energy costs. However, RMP has not performed a study of its trans-  
313 mission assets to determine what percentage is energy-serving (RMP Response  
314 to CCS DR 40.7).

315 **Q: How is PacifiCorp's transmission system designed to reduce energy costs?**

316 A: PacifiCorp's transmission system design lowers energy costs in at least three  
317 ways. First, a large portion of the Company's transmission is required to move  
318 power from the remote generators to the load centers and for export. Were gener-  
319 ation located nearer to the load centers, the long, expensive transmission lines  
320 would not be required (and transmission losses would be smaller). These trans-  
321 mission costs were incurred as part of the tradeoff against the higher operating  
322 costs of plants that could be located nearer to the load centers; in other words as  
323 a tradeoff against energy-related costs.

324 Second, PacifiCorp's transmission system is more expensive because it is  
325 designed to allow for large transfers of energy between neighboring utilities.  
326 Third, PacifiCorp's transmission system is designed to minimize energy losses  
327 and to function over extended hours of high loadings. Were the system designed  
328 only to meet peak demands, a less costly system would suffice; in some cases  
329 lines or circuits would not be required, voltage levels could be lower, and fewer  
330 or smaller substations would be needed.

331 Energy efficiency is clearly a primary purpose of the Company's trans-  
332 mission investment plan, as RMP witness Douglas Bennion explains:

333 Rocky Mountain Power must invest in transmission assets to move Com-  
334 pany owned generation to substations and load centers. The Company must  
335 also build transmission facilities to move power generated by others (i.e.  
336 independent power producers) to substations and load centers. In addition,  
337 the Company must build facilities that interconnect with other transmission  
338 and generation providers as it enters into contracts with customers,  
339 generators and shippers that require transmission access. This transmission  
340 infrastructure is essential to enhance efficiencies as daily and seasonal  
341 loads fluctuate. (Bennion Direct Testimony at 5)

342 **Q: Have you performed a comprehensive analysis of the factors driving RMP's**  
343 **transmission investment?**

344 A: No. Such an analysis is quite data-intensive, involving consideration of the uses  
345 of each line, and the effect of energy and long hours of high usage on system  
346 design. That analysis would best be undertaken by RMP with input and review  
347 by interested parties. I recommend the Commission require such an analysis.

348 To give the Commission a sense of the possible impact of correcting the  
349 transmission classification, I reviewed the transmission-line cost data in  
350 PacifiCorp's 2006 FERC Form 1 at 422–423. From PacifiCorp's transmission  
351 maps, it appears that the highest-voltage lines (500 kV, 345 kV, and 230 kV)  
352 primarily connect PacifiCorp's load with remote baseload generation and would  
353 not be needed except to access low-cost energy. Those lines account for 55% of  
354 PacifiCorp's gross transmission investment and, since they tend to be newer,  
355 probably a higher percentage of PacifiCorp's net transmission investment.  
356 Hence, over half of PacifiCorp transmission revenue requirement is likely to be  
357 attributable to energy.

358 5. *Distribution Classification and Allocation factors*

359 **Q: What is the basis for RMP's distribution cost classification and allocation?**

360 A: The Company relies on UP&L's October 1989 Distribution Cost Allocation  
361 Study (provided as an attachment to DR CCS 38.3). The Study (at 11) attempts  
362 to reflect the distribution design guidelines in the selection of classification and  
363 allocation factors:

364 We need to discover the chief characteristics of each of the physical sub-  
365 systems in order to effect an appropriate cost classification. To do this we  
366 will examine the design process for the distribution system. The rationale  
367 behind this approach is that costs are not driven directly by service  
368 characteristics but by the design engineer's response to those service  
369 characteristics.

370 **Q: How does RMP's COS Study classify distribution?**

371 A: The Company classifies substations, primary lines, line transformers and  
372 secondary lines as demand-related. The remaining distribution plant, services  
373 and meters, are classified as customer-related. In RMP's view, "there are no  
374 significant energy related costs associated with the distribution system."  
375 (Exhibit RMP\_\_\_(CCP-3S), Tab 1, at 8.)

376 **Q: How does RMP's COS Study allocate demand-related distribution plant?**

377 A: The COS Study treats distribution costs as follows:

378 • Substations and primary lines are allocated based on weighted monthly  
379 coincident distribution peaks:

380 The coincident distribution peak is the simultaneous combined  
381 demand of all distribution voltage customers at the hour of the  
382 distribution system peak. These monthly values are weighted by the  
383 percent of substations that achieve their annual peak in each month of  
384 the year. (Exh. RMP (CCP-35), Tab 1, at 9)

385 • Line transformers and secondary lines are allocated based on weighted  
386 non-coincident peaks. In the case of line transformers,

387                   The allocation factor, F21, is based on the maximum monthly class  
388                   NCP. This may be a different month for each class. For classes of  
389                   customers where transformers are shared by more than one customer,  
390                   the NCP is weighted by the appropriate coincidence factor from the  
391                   Company's Job Designer's Manual to recognize the diversity of load  
392                   at the transformer. (Exh. RMP (CCP-35), Tab 1, at 9)

393                   Secondary lines are allocated to the residential and small General Service  
394                   classes only, using a similar "weighted non-coincident peak" allocator.

395   **Q: How does RMP allocate services and meters?**

396   A: Services and meters are allocated based on weighted customer number,  
397       weighted by the current installed cost of the equipment.

398   **Q: Does RMP's allocation of distribution costs reasonably reflect cost**  
399       **causation?**

400   A: No. The Company's approach has the following problems:

- 401       • It overlooks many of the ways in which energy usage drives distribution  
402       investment.
- 403       • The weighting factors used in deriving the F20 allocator (for substations  
404       and primary feeders) are not cost based and overweight the July peak.
- 405       • It ignores the sharing by smaller customers of service drops.

406   a) *Energy-Related Distribution Costs*

407   **Q: In what ways does energy use affect distribution costs?**

408   A: Energy use, especially in high-load hours and in off-peak hours on high-load  
409       days, affects distribution investment and outage costs in the following ways:

- 410       • The number of high-load hours determines risk of load loss following  
411       equipment failure, and hence drives investment in redundant equipment to  
412       improve distribution system reliability.
- 413       • The number and extent of overloads determines the life of the insulation on  
414       lines and in transformers (both in substations and in line transformers), and

415 hence the life of the equipment. A transformer that is very heavily loaded  
416 for a couple of hours a year, and lightly loaded in other hours, may well  
417 last 40 years or more, until the enclosure rusts away. A similar transformer  
418 subjected to the same annual peaks, but to many smaller overloads in each  
419 year, may burn out in 20 years.

420 • All energy in high-load hours, and even all hours on high-load days, adds  
421 to heat buildup and results in (1) sagging of overhead lines, which often  
422 defines the thermal limit on lines; (2) aging of insulation in underground  
423 lines and transformers; and (3) a reduction the ability of lines and  
424 transformers to survive brief load spikes on the same day.

425 • Line losses depend on load in every hour (marginal line losses due to  
426 another kWh of load generally exceed the average loss percentage in that  
427 hour).

428 CSS Exhibit (PLC-8D.2) provides a more detailed explanation of the effect  
429 of energy on the cost and sizing of transformers.

430 **Q: Does the 1989 UP&L study consider the effect of energy use on distribution**  
431 **costs?**

432 A: Yes, but it concludes that the energy-related portion of distribution is negligible.

433 **Q: Is the UP&L study comprehensive?**

434 A: No. The study

435 • limits the category of “energy-related” investments to those that are  
436 specifically made to reduce energy load losses, namely, certain increases in  
437 the sizing of conductors and transformers.<sup>9</sup>

---

<sup>9</sup>In the case of conductors, the UP&L study (at 14) specifies that Company selects the conductor size at the point at which

438 • credits energy loss reductions with fuel-savings only, assuming that only  
439 demand-loss reductions can avoid generation, transmission and distribution  
440 capacity costs.<sup>10</sup>

441 • relies on an out-of-date 1983 estimate of fuel-savings, which is likely to be  
442 much less than current marginal fuel costs and market prices. The lower  
443 the value of fuel-savings from increased capacity of lines and transformers,  
444 the smaller the portion of plant that will be considered energy-related.

445 In addition, UP&L performed few actual calculations to quantify the  
446 energy-related portion of distribution. Apparently, its conclusion was based on a  
447 cost comparison for only two transformer ratings and a single manufacturer,  
448 which UP&L acknowledged (in its 1989 Distribution Study at 21) “cannot be  
449 extrapolated to all transformers....” There were no calculations of the energy-  
450 related portion of conductor costs.

451 **Q: Do the Company’s distribution guidelines and COS Study support the**  
452 **UP&L Distribution Study methodology and conclusions?**

453 A: No, for the following reasons:

454 • Utah Power & Light’s assumption that reduction in energy losses saves  
455 only fuel costs is inconsistent with the Company’s own cost allocation  
456 approach. The COS Study assumes that 25% of generation plant, transmis-  
457 sion plant and firm purchase costs are driven by energy use.

---

...the incremental savings in capitalized energy losses from switching to the next larger conductor are equal to the incremental cost of installing the larger conductor. Thus the conductor selected is the most economical one to use for the initial loading of the circuit.

<sup>10</sup>This also appears to have been a problem with the 1983 version of “Distribution Specification No. L-100: Distribution Transformer Loss Evaluation,” on which UP&L’s distribution-cost allocation relied. Presumably, the Company has revised its transformer purchase practices to take into account the current power market and value of reducing energy usage.

- 458       • The Study misinterprets the distribution design guidelines.
- 459       • The Study overlooks the effect of energy use on the need for replacement
- 460             and the failure rate of distribution equipment, also recognized in the
- 461             distribution guidelines.
- 462       • The Study does not reflect the current condition of the RMP distribution
- 463             system.

464   **Q: Can you provide some examples from the distribution design guidelines**

465             **that demonstrate that energy use is a driving factor in distribution capacity**

466             **costs?**

467   A: Yes. The Study identifies a number of ways in which expected energy use,

468             especially in hours close to peak in load or time, affects both design standards

469             and investment. For example, the sizing of new conductors and transformers is

470             determined by the expected hours of high use as well as by the single peak.

471             Figure 4 of the Guidelines sets out the maximum design loading without damage

472             assuming four hours of usage and maximum emergency usage limited to 8 hours

473             with some risk of equipment damage. So the greater the number of hours of

474             maximum loading, the larger the conductor installed. Similarly, the Study (at 12)

475             recognizes that heat buildup may limit the capacity of a substation transformer.

476   *b) Coincident Distribution Peak Weighting Factors*

477   **Q: Why are the distribution weighting factors invalid?**

478   A: RMP's approach produces illogical results. The only two months with weights

479             greater than 10% are July (41%) and June (18.4%). The Utah distribution peak

480             actually occurs in August, but receives a weight of only 8.5% (Excel file COS

481             UT Dec 2008 (MSP).xls, Tab "Dist. Factors").

482             Weighting by the number of substations peaking in a month does not

483             reflect cost causality. Under this weighting scheme, for example,

- 484       • The month with the most large substations seriously overloaded could be  
485       the highest cost month yet not receive the highest weight.
- 486       • A month would receive a weight of 100% whether each substation's  
487       maximum load were (1) only 1 kVA more than its maximum in every other  
488       month, or (2) four times its maximum in every other month.
- 489       • A small substation has as much effect on a month's weighting factor as a  
490       large substation does.

491   **Q: Are there more reasonable distribution weighting factors the Commission**  
492   **should consider adopting?**

493   A: Yes. I looked at two methods that recognize the size of individual substations  
494   and the effect of multiple peaks on substation sizing.<sup>11</sup> For the first method, I  
495   computed the ratio of the monthly peak on the substation to the annual peak on  
496   the substation, from Attachment CCS 10.28, squared the result so as to rapidly  
497   reduce the contribution as load falls, and summed the squares over the  
498   substations to derive the monthly weights. The second approach is similar, but  
499   starts with the ratio of the monthly peak on the substation (in MW) to the  
500   substation's capacity (in MVA). The resulting monthly weights are as follows:

---

<sup>11</sup>In both cases, I omitted substations for which PacifiCorp provided less than twelve months of data.

501

**Table 5**

	<b>Method for Assigning Substation Costs to Months</b>	
	<i>Squared % of Annual Peak</i>	<i>Squared % of Capacity</i>
<i>January</i>	7.1%	7.1%
<i>February</i>	6.4%	6.4%
<i>March</i>	6.0%	5.9%
<i>April</i>	6.8%	6.7%
<i>May</i>	8.1%	8.2%
<i>June</i>	11.6%	11.9%
<i>July</i>	12.8%	12.8%
<i>August</i>	11.6%	11.9%
<i>September</i>	9.4%	9.5%
<i>October</i>	5.9%	5.9%
<i>November</i>	7.1%	6.7%
<i>December</i>	7.4%	7.0%

502                    Unfortunately, I do not have the data necessary to incorporate the number  
503 of high-load hours in each month into the allocation.

504    **Q: How much would these monthly weights change the allocation of RMP**  
505 **costs?**

506    A: Substituting either of these weights would shift about \$16.4 million off of  
507 Schedules 1 and 10, and about \$16.2 million onto Schedules 6, 8, and 23.

508    **Table 6**

	<b>Schedule</b>	<b>Change in Allocation (Million \$)</b>
<i>Residential</i>	1	-15.4
<i>GS Dist—Large</i>	6	12.4
<i>GS Dist— &gt; 1MW</i>	8	2.0
<i>GS Trans</i>	9	0.0
<i>Irrigation</i>	10	-1.0

509 In addition, the allocation of distribution costs should reflect the extent to  
510 which energy use affects distribution costs.

511 *c) Sharing of Service Drops*

512 **Q: How does RMP allocate service drops?**

513 A: They are allocated based on customer number, weighting by the cost of a new  
514 service for each type of customer (Exhibit RMP\_\_(CCP-3S), Tab 1, at 9).

515 **Q: Has RMP considered the sharing of service drops in developing the service  
516 allocator?**

517 A: No. It assumes that each residential customer requires its own service drop  
518 (RMP Response to CCS DR 10.14) and ignores the sharing of services by  
519 customers in multi-family buildings. The Company has not estimated the number  
520 of shared services or portion of its residential customers that are in multi-family  
521 buildings or the number of service drops installed (RMP Response to CCS DRs  
522 10.11, 10.13).

523 **Q: Have you estimated what the impact of shared services would be on the  
524 residential services allocator?**

525 A: No. RMP does not have data on the mix of housing types and the number of  
526 customers per service in its Utah jurisdiction. However, census information  
527 indicates about 23% of housing in Utah is multi-family. According to the 2000  
528 Census of Housing in Utah, 12.9% of the customers are in multi-family housing  
529 with two to nine units, and 10.3% in multi-family housing with more than nine  
530 units, as follows:

531

**Table 7**

**Units in Structure**

<i>1-unit, detached</i>	520,101	71.5%
<i>1-unit, attached</i>	37,902	5.2%
<i>2 units</i>	29,243	4.0%
<i>3 or 4 units</i>	36,998	5.1%
<i>5 to 9 units</i>	27,677	3.8%
<i>10 to 19 units</i>	30,357	4.2%
<i>20 or more units</i>	44,848	6.2%
<b>Total housing units</b>	<b>727,126</b>	<b>100.0%</b>
<b>Units in multi-family housing</b>	<b>169,123</b>	<b>23.3%</b>

532

Depending on the number of units in each category sharing services, the

533

total number of services to residential customers may well be 20% less than

534

RMP assumes for allocation purposes.

535

**Q: Would similar adjustments apply to other classes?**

536

A: No. Other than multi-family residential customers on the residential rate, rela-

537

tively few customers are likely to share services.<sup>12</sup>

538

**B. Irrigation Class Load Study**

539

**Q: What does the new load study indicate for Irrigation customers?**

540

A: The Company's current COS Study, which relies on this new load data, indicates

541

that bringing the class to the Company average ROR would require at least a

542

30% increase to Schedule 10. The Company is proposing an increase of twice

543

the jurisdictional average request for Schedule 10.

544

**Q: Does the irrigation class present special load research challenges?**

---

<sup>12</sup>In some cases, small commercial customers in a strip mall or office building will share a service.

545 A: Yes. The irrigation loads are diverse, highly variable from year to year, and hard  
546 to characterize. Recognizing this variability, RMP used an unusually large  
547 sample size.

548 **Q: Please explain the derivation of the irrigation load estimates from the**  
549 **sample data.**

550 A: The Company metered the hourly loads of 120 (out of 2,000) irrigation cus-  
551 tomers for the period July 1 through September 15, 2006 and May 25 through  
552 June 30 2007. It extrapolated from the sample to the entire class in the following  
553 five steps (as documented in CCS 23.4 and Attachment DR CCS 10.2):

- 554 1. In each strata, computed the average sample load in each hour;
- 555 2. Calculated a weighted sum of the hourly kWh over the strata to give an  
556 estimate of total class load in that hour, weighting the loads in a given  
557 strata by the percentage of the total population that fall in that strata;
- 558 3. Summed the class estimated hourly loads over all hours to produce an  
559 estimated total class load in each month;
- 560 4. Computed the ratio of the actual to the estimated total class load by month;
- 561 5. Adjusted each estimated hourly load by the ratio computed in the previous  
562 step to provide the load assumptions used in the COS Study.

563 In the off-peak months, RMP calculated the CP (and all other hourly loads)  
564 as the total kWh usage for the month divided by the number of hours in the  
565 month, assuming that in their low usage months, they have 100% load factors.

566 **Q: Does the irrigation customer load data provide a valid basis for cost**  
567 **allocation?**

568 A: No. As can be seen from the ratios provided in Attachment DR CCS 10.2 (Tab  
569 PricingAdj7), there are sizeable discrepancies between estimated and actual

570 monthly usage. The excess of estimated over actual usage in the summer months  
571 range from 7% in July to 75% in September:

572 **Table 8**

	<b>May</b>	<b>June</b>	<b>July</b>	<b>August</b>	<b>September</b>
<i>Load Research (kWh)</i>	44,565	48,669	39,758	44,099	33,430
<i>Pricing (kWh)</i>	35,418	38,735	37,081	33,885	19,062
<i>Adj. Factor</i>	0.79	0.80	0.93	0.77	0.57
<i>Overestimate</i>	26%	26%	7%	30%	75%

573 The load research data over-predicts actual annual usage of irrigation  
574 customers by 24%.

575 **Q: Can RMP's pro rata adjustment to load in all hours provide an adequate**  
576 **correction to the estimated irrigation loads?**

577 A: No. In its derivation of the class hourly load estimates from the sample load data  
578 (as explained above), RMP's adjustment holds load shape constant. In other  
579 words, RMP assumes that the class demand factors are in constant proportion to  
580 energy use and the load profile is unaffected, no matter what the cause of the  
581 discrepancy. This is an unrealistic assumption, especially in the case of  
582 discrepancies as large as 25–75%. The factors that significantly alter kWh usage  
583 (such as crop rotations, changes in weather, temperature and rainfall, and  
584 customer diversity) are likely also to affect load shape.

585 **Q: Does the COS Study support RMP's proposed disproportionate increase in**  
586 **Irrigation rates?**

587 A: No. RMP's irrigation load study represents a serious research effort, but since  
588 there is such a large disparity between sample and actual usage, the data should  
589 not be relied upon to support a major cost allocation action. As discussed earlier  
590 in my testimony, the problem is compounded by the significant under-allocation  
591 of off-system firm sales revenue to this class.

592 **IV. Rate Design Proposal for Residential Schedule 1**

593 **Q: Were you asked by the Committee to address certain issues relating to**  
594 **RMP's residential rate design proposals?**

595 A. Yes. My testimony addresses (1) concerns with the Company's Customer Load  
596 Charge proposal, (2) whether RMP's proposed increase in the customer charge  
597 may over-recover costs from small residential customers in multi-family build-  
598 ings with shared services, and (3) the level of the summer tail-block charge.

599 **Q: What are your general concerns with regard to RMP's residential rate**  
600 **design proposals?**

601 A: Variable energy charges are better at signaling energy-related costs than a fixed  
602 charge that customers cannot avoid. The Company's proposal to collect approxi-  
603 mately 83% of the residential class increase in fixed charges (customer charge  
604 and CLC) will reduce customer control over bills, reduce savings from DSM  
605 investments, and therefore reduce incentives for customers to conserve. Raising  
606 fixed charges is the wrong direction to go especially during a time of rising  
607 energy costs and ongoing concerns about Utah load growth.

608 *1. Customer Load Charge*

609 **Q: Please explain RMP's Customer-Load-Charge ("CLC") Proposal.**

610 A: Under RMP's CLC Proposal, a \$72 charge would be triggered when monthly  
611 usage in the May through September billing months exceeds 1,000 kWh in more  
612 than one month. The CLC would appear in bills as a \$6/month fee for  
613 continuous months upon issuance of the Commission's final order in this case.

614 **Q: What is RMP's rationale for the charge?**

615 A: Company Witness William Griffith claims (at 9–11) that the Company’s pro-  
616 posal will improve residential rate design by providing the following benefits:  
617 • a signal “to large customers about the costs of their above-average usage,”  
618 • a more effective price signal,  
619 • a “strong and persistent” price signal that will appear in every bill rather  
620 than solely in the month in which the kWh usage occurred,  
621 • an easily understandable charge,  
622 • smaller rate increases to the smaller residential customers.

623 **Q: Has RMP provided any studies or reports to support these claims?**

624 A: No. RMP has provided no evidence to support its claim that the CLC will  
625 provide an effective pricing signal. RMP acknowledges (in response to CCS  
626 10.39) that it has not prepared or obtained any of the following analyses or data:  
627 • any study of the relative effectiveness of CLCs versus tail block energy  
628 charges,  
629 • any estimate of the effect of the CLCs on the residential class contribution  
630 to summer peak usage,  
631 • any survey of customers’ understanding or acceptance of CLCs,  
632 • any survey of other utilities’ experience with CLCs,  
633 • any estimate of effect of CLCs on customers’ peak usage.

634 **Q: Did RMP properly assess the bill impacts of the CLC?**

635 A: No. The Company’s bill-impact analysis ignores several of the CLC’s effects,  
636 particularly by computing the bills only for a customer whose usage is the same  
637 from month to month. As a result, the bill-impact analysis adds the CLC to all  
638 bills over 1,000 kWh, and to others. In reality, the CLC would be added to some  
639 small bills (e.g., 400 kWh) and not to some large bills (e.g., 2,000 kWh).

640 **Do you believe that the CLC could provide an effective pricing signal?**

641 A: No, for the following reasons:

- 642 • The charge is not cost-based. Usage during high-load periods is a primary  
643 driver of costs. Yet, customers incur the same \$72 annual cost whether (a)  
644 they consume 2,000 kWh in all four summer months or (b) reach 1,100  
645 kWh in only June and July and use 750 kWh in the other two months. In  
646 the extreme, a customer could end up paying \$72 for a single kWh. On the  
647 other hand, a customer with very high usage in only one month (e.g., 4,000  
648 kWh in the peak summer month) will not incur the \$72 penalty. The CLC  
649 is inequitable, assigning the highest penalty per kWh to the customers with  
650 the lowest increment above 1000 kWh.
- 651 • Once incurred, the CLC will provide no incentive to conserve, even at  
652 peak times.
- 653 • Shifting revenues onto fixed charges will reduce energy charges and  
654 encourage increased summer electric use.
- 655 • If the CLC does provoke a response, it is more likely to come from the  
656 customers nearer the 1,000-kWh breakpoint. A small percentage reduction  
657 in load would be enough to avoid the charge, providing a significant  
658 reward for a relatively small effort. But for a 2,000 kWh residential  
659 customer with a very high air conditioning usage, a savings of \$72 would  
660 probably not be worth the effort required to reduce usage by 50%.
- 661 • The CLC cannot be easily explained to customers, especially since it  
662 violates fundamental cost and fairness principles. Customers will have  
663 difficulty accepting fixed charges in winter bills that are in payment for  
664 high summer consumption.
- 665 • The CLC will be difficult to avoid. Determining whether to reduce usage is  
666 inherently difficult, since the customer must know (1) the start and stop  
667 date of the billing month and (2) its summer monthly usage. In addition,

668 the customer must on a daily basis (1) monitor usage so far in the billing  
669 month and (2) forecast usage in the remaining days of the billing month,  
670 under normal and various alternative operating conditions. In fact, in its  
671 survey RMP found that at least 67% of its residential customers do not  
672 know their billing cycle or their monthly usage—information that would  
673 be crucial to customer success at avoiding the CLC trigger.

674 • The CLC would be difficult, if not impossible, to implement. The kWh  
675 billing determinants in a given month are not entirely under customers’  
676 control. Customers are placed into one of 21 different billing cycles  
677 (RMP’s Response to AARP DR 4.1). Some of the electric bills are  
678 calculated based on estimated rather than actual billing data because of  
679 missed meter readings, meter reading errors, and meter failures. On the  
680 other hand, a summer meter reading (and bill) can reflect anywhere from  
681 26 to 34 days’ electric use with no adjustment for the length of the billing  
682 period (RMP’s Responses to AARP DR 4.2, 4.3). These factors are not  
683 generally a problem under the current residential rate, because the bills are  
684 self-correcting. When the actual kWh reading is billed, any prior  
685 misestimates are netted out in the following bill. On the other hand, the  
686 CLC is a spike in price that is fixed once incurred. When a small error in  
687 billing can result in a permanent \$72 overcharge, there will be considerable  
688 customer frustration and billing disputes.

689 **Q: Please explain why billing cycles can cause problems.**

690 A: Suppose there are two customers A and B that have the same daily load profile  
691 but are billed on two different billing cycles X and Y. Billing cycle X includes  
692 ten hot days in each of two months, and Y includes 15 hot days in the first  
693 month and five days in the second month. Customer A has an 1,200 kWh bill in

694 the first month but only 900 kWh in the second, while Customer B has two 1050  
695 kWh in both months. As a result, only Customer B must pay the CLC.

696 2. *Customer Charge Increase*

697 **Q: What is the Company's basis for doubling the customer charge to \$4 per**  
698 **month?**

699 A: The Company proposes to set the customer charge to recover the embedded  
700 costs of meters, service drops, meter reading, and billing for residential  
701 customers (Griffith Direct at 6–7). Exhibit RMP\_\_\_(WRG-3S) derives an  
702 average cost per residential customer from the COS Study.

703 **Q: Is it appropriate to set the customer charge at the average cost of the**  
704 **components you listed in the previous response?**

705 A: Only if those costs are independent of the size of the customer (Commission  
706 Order, Docket No. 06-035-21, p. 30). Costs that vary with usage should be in the  
707 energy charge. Only the costs of serving the smallest customers should be in the  
708 customer charge. Otherwise, small customers would subsidize large customers.

709 **Q: Do any of the components of RMP's calculation of the customer charge**  
710 **overstate the cost of serving small customers?**

711 A: Yes. The smallest residential customers are likely to live in multi-family  
712 housing. Those smaller customers would likely share a service drop with other  
713 customers in an apartment building. The cost of the service drop varies with the  
714 load of the building, not with the number of customers, and therefore does not  
715 belong in the customer charge.

716 Meter reading costs that are also included in the customer charge vary with  
717 the size and type of customer. In an apartment building, a single meter in a bank

718 of meters is likely to require much less meter reading time than a single family  
719 home.

720 **Q: Have you estimated a customer charge reflecting only the costs of**  
721 **minimum-size residential customers in multi-family housing?**

722 A: Yes. To estimate the customer costs for customers living in multi-family  
723 dwellings, I made just one change in RMP's calculation: I removed the costs of  
724 service drops. This change alone (without any adjustment to the meter reading  
725 cost estimates) results in a customer charge of \$2.40 per month.

726 3. *Summer Tail Block Charge*

727 **Q: How do you recommend that the revenue increase be recovered from**  
728 **residential customers, if not through a CLC and increase in the customer**  
729 **charge?**

730 A: This cost should be recovered in the energy charges, with the longer-term goal  
731 of moving the tail block to marginal cost.

732 **Q: What is the cost of serving the summer tail-block load?**

733 A: Additional summer load incurs the following costs, among others:

- 734 • summer energy costs, much of it in high-load, high-cost hours, especially  
735 for customers in the tail block;
- 736 • a large portion of the cost of peaking generation capacity, including  
737 reserves;
- 738 • a large portion of the incremental costs of transmission and distribution;
- 739 • line losses.

740 **Q: Can you quantify those costs at this time?**

741 A: In part. As of early June, the forward prices for third-quarter energy at Palo  
742 Verde and Mid-Columbia in 2009 and 2010 were running about 11¢/kWh on-  
743 peak and 7¢/kWh off-peak. Even for a nearly flat load shape, with 60% of the  
744 energy in the peak period, the average summer market value of the power is  
745 about 9¢/kWh.<sup>13</sup> For a real residential load shape, the energy costs would be  
746 greater. Peaking capacity, at \$48/kW-year for a frame combustion turbine (in  
747 2006 dollars, from the 2007 IRP), to meet peak plus a 12% reserve margin,  
748 spread over 1,400 summer kWh per kW of peak, would add another 1¢–  
749 2¢/kWh.<sup>14</sup> Including even 10% marginal losses, the total generation cost would  
750 be between 11¢ and 12¢/kWh. Marginal load-related T&D costs would add  
751 another couple cents per kWh.<sup>15</sup>

752 **Q: Please summarize your recommendations.**

753 A: On the cost-of-service study, I recommend in Section III.A improvements in  
754 classifications and allocations, specifically:

- 755 • classifying a greater percentage of fixed non-seasonal generation costs as  
756 energy-related,
- 757 • classifying a greater percentage of non-seasonal purchases as energy-  
758 related,
- 759 • classifying a greater percentage of transmission costs as energy-related,
- 760 • allocating firm sales revenues in a more realistic manner,
- 761 • classifying a portion of distribution costs as energy-related,

---

<sup>13</sup>About 57% of hours are in the peak period.

<sup>14</sup>I assume that a flat energy forward would provide capacity value at the average load level; peaking would be required to make up the difference.

<sup>15</sup>On the other hand, some of the generation capacity is attributable to months outside the summer.

- 762           • recognizing the sharing of service drops by small residential customers,  
763           • revising the monthly weights for the primary distribution allocator.

764           My recommended changes to the classifications and allocations should be  
765 addressed in an appropriate forum and implemented in the Company's next  
766 COS Study.

767           In setting the rate spread, the Commission should recognize that the  
768 deficiencies in the COS allocations and in the irrigation load study bias the COS  
769 results and in particular tend to overstate the costs of Schedule 1, 10, and 23.  
770 Since the COS Study is flawed in a number of areas, it should not be relied on  
771 for determining rate spread until these problems are corrected. In his testimony,  
772 Mr. Gimble discusses the Committee's rate spread proposals in greater detail.

773           In residential rate design, the Commission should reject RMP's proposed  
774 CLC and customer charge increase, and use the revenues to raise energy  
775 charges, especially in the summer tail block.

776   **Q: Does this conclude your testimony?**

777   **A: Yes.**
