

1 **Q. Please state your name, address and current position.**

2 A. My name is Frank C. Graves. I am a principal of *The Brattle Group*. My business  
3 address is 44 Brattle Street, Cambridge, Massachusetts 02138.

4 **Q. Have you previously testified in this proceeding?**

5 A. Yes, I submitted prepared supplemental testimony in this proceeding on behalf of  
6 Rocky Mountain Power (“RMP” or “Company”) on August 12, 2009.

7 **Q. What is the purpose of your rebuttal testimony?**

8 A. I respond to various intervenors who assert that:

- 9 • the overall need for an ECAM has not been established;
- 10 • an ECAM is not needed in light of RMP’s gas and power hedging practices;
- 11 • incentives to operate efficiently will be lost under an ECAM;
- 12 • implementation of an ECAM requires a reduction to RMP’s cost of capital
- 13 • an ECAM should not be adopted until RMP’s hedging practices and reliance on  
14 market energy have been addressed and resolved

15 **Q. Please summarize your conclusory responses to these intervenors.**

16 A. The need for an ECAM is clear from the substantial, intrinsic uncertainty that  
17 RMP faces with respect to its net power costs (NPC). RMP’s hedging practices do  
18 not and cannot eliminate enough volatility in NPC to make an ECAM  
19 unnecessary. In particular, two components of NPC—net short-term sales revenue  
20 and natural gas expenses—exhibit so much variability that an ECAM-like  
21 mechanism will be needed to protect RMP and its customers, even with RMP’s  
22 substantial hedging practices. These two components of NPC are also extremely  
23 difficult to forecast, with the result being that past rate case projections of total

24 NPC have had annualized variances between actual and allowed costs of up to  
25 \$300 million or more, on a total system basis. Moreover, there is no reason to  
26 think that variances between forecasts and actuals in one component of NPC  
27 necessarily will be offset by variances in other components in NPC, or that  
28 forecast variances will be short-lived or symmetrical around a mean of zero over a  
29 few years. These differences have the potential to be persistent and systematic  
30 such that significant under-recoveries or over-recoveries of NPC are possible,  
31 with the potential for financial harm to either RMP or its customers. In recent past  
32 years, the tendency seems to have been for the settlement forecasts to understate  
33 eventual costs, often dramatically. An ECAM will not improve the forecasts, but  
34 it will ensure that RMP is compensated precisely for the net fuel and power  
35 expenses it incurs on behalf of its customers, without any over- or under-recovery  
36 of these costs.

37 **I. HEDGING CANNOT CONTROL RISKS SUFFICIENTLY TO**  
38 **ELIMINATE THE NEED FOR AN ECAM**

39 **Q. What arguments have been raised by intervenors to suggest that an ECAM is**  
40 **not needed or is not in the public interest?**

41 A. Mr. Paul Chernick claims that RMP has failed to provide a quantitative analysis  
42 of the magnitude and nature of the factors driving fluctuations in its NPC and that  
43 RMP “grossly exaggerates” the uncontrollable risks to which RMP is exposed  
44 without an ECAM.<sup>1</sup> He claims that even if RMP had been exposed to gas and  
45 electric price risks in 2002-2008, it is protected from price swings because of its

---

<sup>1</sup> Direct Testimony of Paul Chernick, p. 5 (lines 117-121).

46 gas and electricity hedging practices.<sup>2</sup> Mr. Kevin C. Higgins also finds that as a  
47 result of its hedging practices, RMP’s cost structure is not sufficiently volatile to  
48 justify adoption of an ECAM.<sup>3</sup> Mr. Charles E. Peterson similarly believes that  
49 RMP has not been “entirely persuasive” in supporting the need for an ECAM,  
50 though he does recommend moving forward to Phase II of the proceeding to sort  
51 out design and implementation issues because some type of ECAM may be in the  
52 public interest.<sup>4</sup> He claims that RMP has substantially shielded itself from  
53 volatility in spot market prices in electricity and gas through its hedging practices  
54 and that RMP has not shown how volatility affects the Company’s earnings.<sup>5</sup>  
55 Importantly, none of these intervenors offer a theory of what threshold of risk has  
56 to be crossed before they would deem the situation worthy of an ECAM, nor have  
57 any of them analyzed actual financial performance or the shifting (and increasing)  
58 nature of electric power market risks over the past few years and likely into the  
59 future.

60 **Q. How do you respond to these claims?**

61 A. I disagree with the suggestion that RMP’s hedging practices make an ECAM  
62 unnecessary and that RMP has exaggerated the uncontrollable risks to which it is  
63 exposed. The need for an ECAM can be seen in the significant uncertainty RMP  
64 faces with respect to at least two major components of its net power costs,  
65 specifically net revenues from short-term power sales and purchases (that are a  
66 deduction from RMP’s NPC given RMP’s position as a net seller of energy but

67 not capacity) and natural gas expenses. These components are sources of  
68 considerable NPC risk for RMP—risk that it cannot control to any significant  
69 degree.

70 At the time it files a general rate case, RMP makes projections of these two  
71 components (and other factors) of its net power costs, but there is unavoidable  
72 uncertainty as to both their realized volumes and the prices at which they will  
73 occur. The price component is very uncertain because spot prices are highly  
74 volatile and almost certain to diverge from prior forward prices. Indeed, forward  
75 prices themselves change rapidly, making the forecasting process highly  
76 dependent on the dates when the analysis and filing occur. The volumes for short-  
77 term sales and purchases and for natural gas expense in turn depend on the  
78 realized spot prices, and on complex, shifting supply conditions. There are simply  
79 too many unknowns to expect RMP to make a clairvoyant forecast of these items  
80 that will reliably have small variances from actuals. Moreover, NPC rates are not  
81 set based strictly on RMP's own, most timely projections prevailing just before  
82 the filing. Instead, they reflect lags in a process that includes the opinions of  
83 intervenors about how markets may evolve or how the PacifiCorp system may be  
84 operated. The historical evidence presented by Mr. Gregory N. Duvall  
85 demonstrates that the resulting variances have been large and have lead to  
86 substantial under-recovery of RMP's NPC (though in principle over-recovery  
87 could also occur).

88 Moreover, for some of the same reasons that these items are difficult to forecast  
89 (especially the highly uncertain volumes) RMP's hedging practices cannot make

90 this uncertainty go away, nor could a better forecasting model. At best, one can  
91 project these costs within a broad confidence interval reflecting the uncertainty in  
92 the short-term power and gas markets. An ECAM is necessary to capture these  
93 variances and ensure accurate recovery of incurred costs.

94 **Q. Please describe your analysis of how net short-term power sales revenues and**  
95 **natural gas expenses contribute to NPC?**

96 A. I have developed some summary statistics on the major components of projected  
97 NPC since 2001 for PacifiCorp as a whole (the level at which NPC is managed).  
98 These values are taken from Exhibit RMP\_\_\_\_(GND-1R) (described in the rebuttal  
99 testimony of Mr. Duvall) and they are presented as tables in my Figures 1, 3, 4,  
100 and 5 throughout this testimony. I have simply normalized his data to put it on an  
101 annualized (12-month, not calendar) basis, and then I have calculated some ratios  
102 that show how much certain cost components contributed to NPC. This analysis  
103 describes the annualized costs that were projected (or realized, in some rows) on  
104 average over a 12-month period for the items in a given NPC filing, averaging  
105 across all the months between filings.

106 The “projected” rows in my analyses are calculated as if the rates approved in the  
107 RMP filings applied to the entire PacifiCorp system, in order to show  
108 conceptually how much of an economic gap there would be for the corporation as  
109 a whole if all of its cost recovery was based on Utah RMP rates. In fact, this is not  
110 the case, as some of the other PacifiCorp state jurisdictions have ECAM-like  
111 adjustment clauses that protect against the kinds of variances seen in this chart.  
112 RMP in Utah represents approximately 40 percent of PacifiCorp’s total load, so

113 roughly speaking, RMP’s exposure is to that share of these overall variances.

114 **Q. What does your analysis demonstrate about the causes of NPC variability?**

115 A. The first four rows of Figure 1 below show the three major components of NPC to

116 have been net short-term sales revenues (the difference between short-term sales

117 and short-term purchases, labeled “NSR” herein for convenience), gas expenses,

118 and other expenses (mostly coal operating costs, long term power purchases and

119 sales, and fuel contracts). Rows 5 and 6 show that NSR and gas expenses have

120 made up a significant portion of forecasted annual NPC.

\*Figures may not add up due to rounding.

\*\*Expenses that reduce net income and increase NPC are shown as negative numbers.

\*\*\*Other expenses include coal operating costs, long term power purchases and sales, and fuel contracts.

121 Specifically, projected NSR has ranged from negative \$218 million (i.e. net

122 purchases) in 2001 to as much as positive \$669 million most recently, or as much

123 as negative 65 percent, of annual NPC, which itself has been a bit above \$1

124 billion per year at the time of the more recent rate cases. NSR is usually a

125 negative percentage of NPC because it serves to lower NPC. This happens

126 because, since 2001, RMP has projected it will earn net positive sales margins

127 (from its short-term balancing sales in excess of purchases) with the net revenues

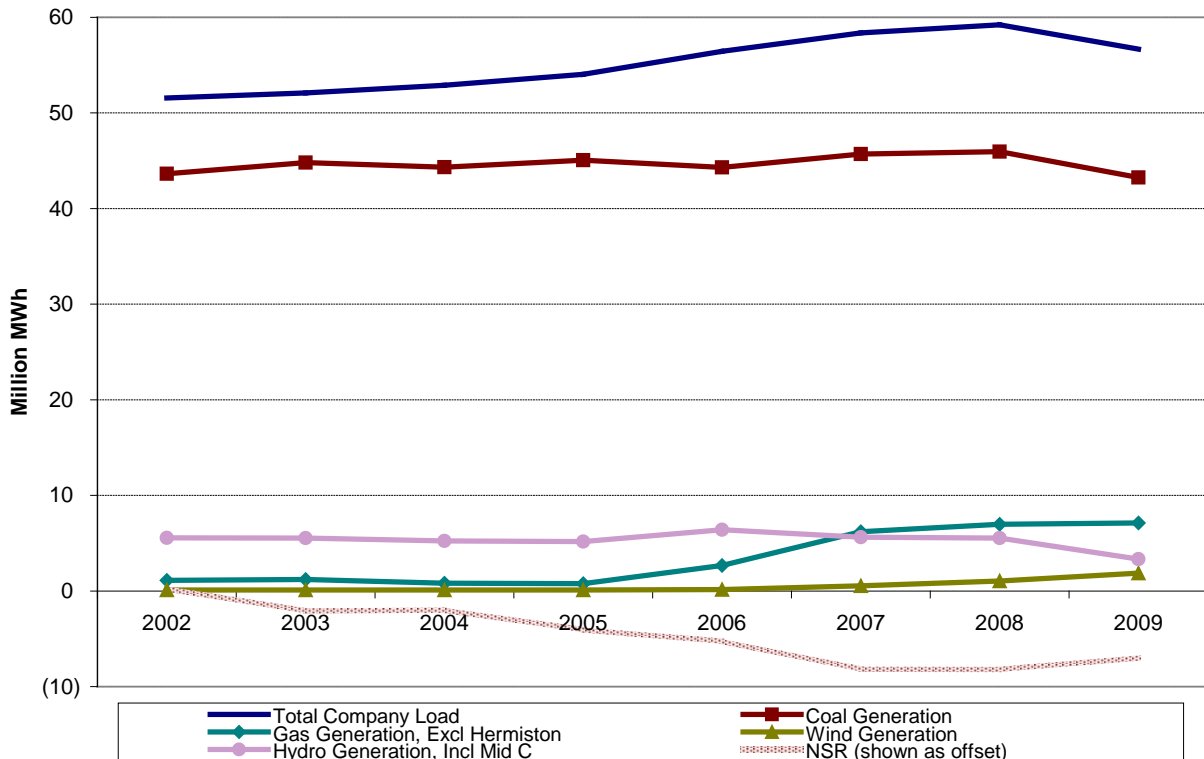

128 credited against the other expenses that make up NPC. For instance, in Docket  
129 No. 06-035-21, RMP filed a rate case in which it projected \$1,076 million in  
130 short-term market sales, less \$549 million of projected purchases, for a net of  
131 \$527 million shown in Row 1, Column D of Figure 1. This amount was used to  
132 reduce roughly \$1.34 billion in gas and other operating expenses, for an overall  
133 NPC of about \$813 million.

134 Likewise, RMP's natural gas expenses are a significant portion of NPC, which  
135 has grown significantly over the past decade as more gas resources have been  
136 added to the PacifiCorp supply portfolio. Gas expenses have accounted for  
137 roughly \$181 to \$467 million or 22 to 45 percent of annual NPC in recent rate  
138 cases.

139 **Q. Is there evidence that RMP is increasingly relying on resources whose costs**  
140 **are difficult to forecast?**

141 A. Yes. Figure 2 below shows the actual annual load and key resources on the RMP  
142 system during most of this decade. Loads have been growing over the course of  
143 the decade, while coal-fired generation has remained a relatively stable source of  
144 supply, operating at similar levels to those of the early part of the decade.  
145 Therefore, these expanded obligations are being met increasingly by gas-fired  
146 generation and renewable resources. Also shown in this figure is a line below the  
147 x-axis that shows the NPC offsets from NSR.

Figure 2  
Generation Mix and Load (Million MWh)

Note: 2009 figures are scaled up to annualize 9 months of actual data.

148 **Q. Why are short term sales and purchases difficult to forecast?**

149 A. These transactions are for “balancing” the system via selling residual power to the  
 150 wholesale market in off-peak periods when it is not needed for native load, and  
 151 buying supplemental power when owned resources are not enough, or the  
 152 PacifiCorp marginal units are not as economical as market sources, to meet native  
 153 load requirements. This balancing takes place opportunistically over hours, days,  
 154 or somewhat longer periods, but not over the forecasting horizon of NPC filings.  
 155 Thus it depends on many factors that simply cannot be known with any precision  
 156 at the time of a rate filing. While RMP can use system models to reasonably  
 157 simulate in advance the hours, quantities and prices at which it expects it will buy

158 and sell balancing electricity, how much it ultimately transacts will depend on  
159 realized short-term supply and demand market conditions in both its service  
160 territory and in adjacent service territories throughout the WECC.

161 For instance, if actual load is higher than was projected in rates, then purchases  
162 (or gas expense) are also likely to be higher. Off-system sales may or may not  
163 then be higher, depending on whether PacifiCorp's generation resources remain  
164 available for resale despite the higher native loads, and on how their operating  
165 costs compare to the marginal cost resources serving the wholesale market. The  
166 latter, in turn, could depend on outages on the Western interconnection system,  
167 transmission constraints, hydro conditions, and many other highly uncertain  
168 variables. There are two important implications of this complexity from being a  
169 residual resource involved in balancing: First, the underlying sales and purchase  
170 volumes are highly conditional and variable from day to day and hour to hour.  
171 This makes them very difficult to hedge accurately, because they are not in any  
172 way similar to standard, fixed volume and fixed price forward contracts for fuel or  
173 power. Second, it makes them very difficult to forecast.

174 **Q. How variable has NSR been in the past few years?**

175 A. It has been extremely variable, in terms of its forecasted vs. actual sales and  
176 purchase volumes, sales and purchase prices, net amounts for each, and overall  
177 NSR projected in-rates versus actual total dollars. The last four rows of Figure 3  
178 show these components over time. The annualized variances between forecasts  
179 and actuals in NSR have ranged from positive \$264 million (actual NSR far  
180 exceeding projected amounts) to negative \$214 million (an NSR shortfall from

181

projected amounts), or from -26 percent to 42 percent of projected NPC in rates.

Sources and Notes:

[1] - [10]: From Rocky Mountain Power.

[11]: [10] - [9]

[12]: [11] / [9]

[13]: [11] / NPC (Table 1, [4]).

\*Figures may not add up due to rounding.

\*\*Expenses that reduce net income and increase NPC are shown as negative numbers.

182

For example, the NSR projected in Column E, Row 9 (following Docket 07-035-

183

93) was \$439 million, but actual NSR was \$264 million higher (roughly \$702

184

million). The variance was -26 percent of the projected NPC (which was about

185

\$1.0 billion) and 60 percent of the projected NSR. The upper rows in this chart

186

break out what caused the variance. The first two rows show projected and actual

187

short term sales volumes, in million MWh/year. Projected sales in this docket

188

were much lower than actual, with 22.0 million MWh sold versus 19.0 million

189

MWh projected. The next two rows show that the average price per MWh at

190

which these sales occurred was roughly \$5/MWh less than projected. Thus, the

191

overall revenues from short term sales were \$1,301 million versus \$1,221 million

192

projected, for an \$80 million variance due to these price and quantity effects

193 combined. The actual short term purchases in that rate period also did not match  
194 the projected amounts in rates, with actuals of \$598 million compared to a  
195 projection of \$783 million, for a net purchase variance of \$185 million. The total  
196 NSR variance of \$264 million is the sum of these two (sales and purchase)  
197 variances, favorable to RMP's cost recovery in the 2007 case. However, such an  
198 offset was not the result arising from the variances in the prior and subsequent  
199 rate settings, in which actual NSR was below projected, contributing to an  
200 annualized under-recovery of total NPC.

201 Studying the rows and columns of Figure 3 reveals large variability in these  
202 components over time. For instance, actual 12-month short-term market sales  
203 have ranged from \$690 million to \$2,192 million and have swung up and down  
204 substantially from rate case to rate case. Likewise, actual short-term market  
205 purchases have varied substantially over time. Thus, NSR credited against other  
206 costs in NPC represents the net value of two huge line items, themselves often  
207 much larger than NPC, and both facing very complex volume and price  
208 forecasting problems.

209 **Q. Have there also been significant variances between forecasts and actuals with**  
210 **respect to the natural gas component of NPC?**

211 A. Yes there have, and for similar reasons to the difficulties in projecting NSR. Gas  
212 generation is also a residual quantity, since it dispatches towards the top of the  
213 merit ladder, after baseload coal, hydro and renewables. And like NSR, gas  
214 expense reflects both complex, conditional short-term volumes and uncertain gas  
215 fuel prices. There is significant uncertainty in the projections for RMP's gas-fired

216 generating units as to how much they will run, how much natural gas they will  
 217 consume, and at what price. Figure 4 below shows that the annualized variances  
 218 have ranged from negative (\$42) to positive \$185 million or +8 to -23 percent of  
 219 projected NPC.

\*Figures may not add up due to rounding.

\*\*Numbers are shown as negative when they decrease NPC and increase net income because gas is an expense in this figure.

220 For example, the gas expenses projected in Column E (again following Docket  
 221 07-035-93) were \$345 million, but actual gas expenses were over \$134 million  
 222 higher (\$479 million). This occurred because actual gas generation was much  
 223 higher than had been projected (7.8 million MWh actual versus 5.7 million MWh  
 224 projected). The result was a large under-recovery, resulting in an additional \$134  
 225 million in gas costs that were not included in the rate case projection for gas  
 226 expenses. (In this period, very little of the variance in gas expense is due to gas  
 227 prices themselves, for which projected and actual values were quite similar.  
 228 However, in other periods, the price variances were large). It is likely that some

229 of this gas variance occurred in lieu of the short-term purchases discussed above,  
230 which were lower than projected over this same time frame. Sometimes, that kind  
231 of NPC variance-dampening relationship will hold (in which gas generation  
232 substitutes for purchases, or gas is used more heavily to cover increased short  
233 term sales), but it need not occur, depending on when and why more purchases or  
234 sales are needed.

235 **Q. Can't gas expenses be hedged fairly readily, given the active markets trading**  
236 **forward at several locations?**

237 A. Yes and no. Fixed volumes of gas can be hedged quite readily, but that does not  
238 describe the RMP usage of this fuel. As explained above, RMP's gas needs arise  
239 from a complex, residual power requirement in the top of the dispatch supply that  
240 can change from day to day due to combinations of natural gas spot prices,  
241 wholesale power prices, and operational reliability considerations. Thus, the  
242 actual volumes of gas ultimately dispatched will depart from the amounts hedged  
243 and in rates, because gas-plant utilization is dependent on short-term system  
244 conditions.

245 Even though the expected gas needs are hedged with forward purchases, the price  
246 paid in such forwards does not determine whether the gas units will be dispatched.  
247 Because there is such an active, liquid spot market in natural gas, it is more  
248 economical for these units to be dispatched according to whether the short-term  
249 price of gas justifies their usage, not according to whether the hedged price would  
250 do so. If the spot price for gas is above the price at which the unit should dispatch,  
251 but the hedged gas is less expensive, the hedged gas itself is sold to the spot gas

252 market rather than used as fuel in the less valuable electric generation; power is  
253 purchased in the spot power markets to replace the gas-fired generation not used.

254 **Q. Do the problems you have identified with respect to forecasting NSR and gas**  
255 **expenses translate into substantial variance between forecasts and actuals for**  
256 **overall NPC?**

257 A. Yes. Figure 5 compares forecasted to actual NPC on both a total cost (millions of  
258 dollars per twelve months) and average cost (\$/MWh) basis. It shows there has  
259 been a substantial gap, almost always adverse to RMP shareholders, between  
260 allowed and actual NPC. The annualized variances are as much as \$308 million in  
261 unrecovered costs, with the differences ranging from +3 percent over-recovery to  
262 -52 percent under-recovery and with only one period out of six in which actual  
263 NPC was below the projected (in-rates) NPC. Column D provides a good  
264 example. In total, actual NPC was \$1.1 billion, compared to projected NPC of  
265 \$813 million—for an under-recovery of \$308 million. This under-recovery is  
266 largely explained by the variability in NSR (\$78 million, see Figure 4) and natural  
267 gas (\$185 million, see Figure 3).

\*Figures may not add up due to rounding.

268 In this particular time period, the variance in natural gas costs was not offset by a  
 269 corresponding variance (in the other direction) of NSR, although that sometimes  
 270 can happen. For instance, in the Column E of Figure 4, a similarly large gas cost  
 271 under-recovery (of \$134 million) was more than offset by the much higher than  
 272 forecast actual NSR (of \$264 million) that I described in Figure 3. As shown in  
 273 Figure 5, the end result in this one instance was an over-recovery in NPC of \$32  
 274 million (See Column E, Row 3). Higher market prices for power might result in  
 275 higher sales and higher gas usage, thereby having one factor offset the other, but  
 276 (as discussed further below) there is no reason to assume that this will occur in  
 277 general.

278 **II. INCREASED DIFFICULTIES IN FORECASTING**

279 **Q. Do changing wholesale market conditions also contribute to the difficulty in**  
 280 **forecasting NPC?**

281 A. Yes, another contributing factor is that wholesale gas and power prices have  
 282 become harder to forecast, even apart from the fact that the quantities needed by

283 RMP are residuals with complex time patterns. Just the price forecasting problem  
284 alone, apart from any volume shaping or timing problems, has become more  
285 difficult in the past few years. Specifically, volatility in gas and power prices has  
286 increased. Figure 6 shows the 6-month rolling volatility of natural gas spot prices  
287 at Opal and the 6-month rolling volatility of electricity peak prices at Palo Verde.  
288 The upper figure shows the annualized percentage day-to-day changes in prices,  
289 while the lower figure shows the volatility of the prices in \$/MWh terms. Both  
290 charts show the increasing volatility over the last few years, but especially the  
291 dollar-denominated charts. (The upper, percentage chart is more typically  
292 reported as a measure of volatility, especially for use by power traders, but the  
293 lower chart in actual price terms is more useful for understanding the variances  
294 RMP has experienced in its NPC collections vs. forecast.)  
295 This increasing volatility of spot prices contributes to the difficulty in projecting  
296 likely NSR volumes and prices, and gas expenses. It means there is an  
297 increasingly wide range of realized spot prices at the time those short-term  
298 transactions actually take place.

Figure 6

6-month Rolling Annualized Returns Volatility for Daily Gas and Electricity Prices

Sources and Notes: Daily Gas data is for Kern River, Opal from Platts Gas Daily and Electricity data is for Palo Verde from IntercontinentalExchange (ICE). Rolling volatility is calculated using the previous 124 observations (roughly 6-month history).

6-month Rolling Daily Price Volatility for Gas and Electricity

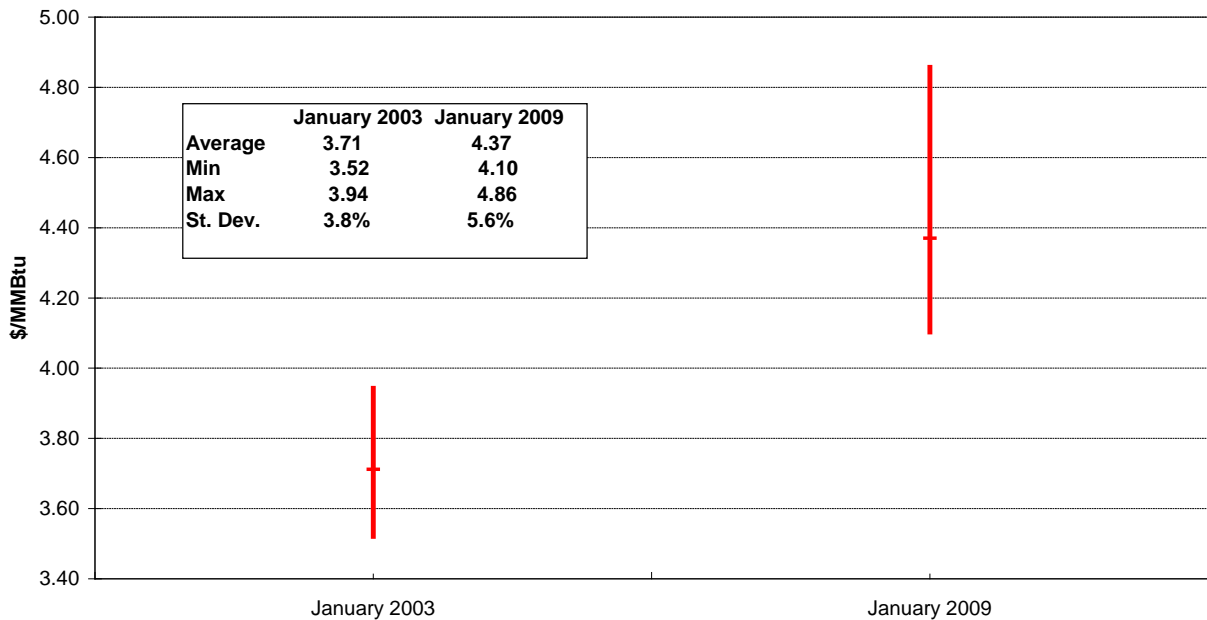

Sources and Notes: Daily Gas data is for Kern River, Opal from Platts Gas Daily and Electricity data is for Palo Verde from IntercontinentalExchange (ICE). Rolling volatility is calculated using the previous 124 observations. Gas prices in \$/MMBtu are converted to \$/MWh at 10,000 heat rate.

299 **Q. What about forward prices? Have they become more volatile as well, and if**  
300 **so, how does that contribute to increased forecasting difficulties?**

301 A. Forward prices for power and natural gas have both become more volatile over  
302 the past few years, consistent with the spot price behavior just discussed. Figure 7  
303 shows some statistics obtained from the recent (January 2009) and historical  
304 (January 2003) daily data on forward gas prices for the Rocky Mountain area at  
305 Opal. This figure shows the average, minimum, maximum and variability  
306 (measured by standard deviation) of the natural gas 12-month forward strip  
307 average price six months ahead of delivery. In January 2003, the average forward  
308 prices of natural gas for delivery at Opal in July 2003 through June 2004 was  
309 \$3.71/MMBtu, the spread between the highest and lowest values was  
310 \$0.42/MMBtu and the standard deviation was 3.8 percent of the average value.  
311 By January 2009, the average forward strip prices had increased by  
312 \$0.66/MMBtu, while the spread between the highest and lowest values had almost  
313 doubled (increased to \$0.76/MMBtu) and the standard deviation increased to 5.6  
314 percent.

Figure 7

**Average, Min and Max of Natural Gas 12-Month Forward Strip for Rock Opal  
(6-Month Ahead Delivery)**

315 The significantly broader range of forward prices in 2009 comparative to 2003  
316 indicates increased uncertainty, which makes the NPC forecasting problem much  
317 more difficult, especially since RMP forecasts its prices primarily based on  
318 market forward prices. That is, even though forward prices may be the current  
319 best estimate of future spot prices, in recent years such estimates have become  
320 increasingly variable from day to day. This means that the prices used as the  
321 anchoring basis for projected NPC prices in a rate case would very likely be  
322 different, perhaps materially so, if they had been based on forward contracts  
323 trading just a day or two earlier or later than the trading dates actually used. Thus,  
324 there is no real hope of reducing NPC risk through “better forecasting.” The  
325 market already impounds the consensus forecast of the marginal traders, day in  
326 and day out, and that forecast has become quite variable.

327 **Q. Does forward price volatility aggravate the risks due to regulatory lag?**

328 A. Yes, forward price volatility creates NPC recovery exposure to the lag between  
329 the start of the test year period and the date when rates go into effect. If rates go  
330 into effect well into or after the test year, the allowed amounts will not reflect the  
331 actual costs of hedges and forward contracts that are new by the time the rates  
332 become effective, instead reflecting the maximum of forward commitments and  
333 hedges in effect during the test year. The greater the volatility of forward  
334 contracts (and the larger the gap between the test year and the effective date of the  
335 rates), the greater the potential variance. In RMP's current rate case, the test year  
336 period is from July 2009 to June 2010, while the associated rates are expected to  
337 go into effect in February 2010, a seven month delay.

338 **Q. Is a similar increased uncertainty observed in forward power prices?**

339 A. Yes, uncertainty in forward power prices has also increased over the last couple of  
340 years. Figures 8 and 9 show the increased variability in the 12-month forward  
341 strip trading six months ahead of delivery for on-peak and off-peak contracts at  
342 Palo Verde. The average peak-hours' electricity forward price increased by  
343 \$4.96/MWh from January 2003 to January 2009, i.e. by about 10 percent, while  
344 the difference between the highest and lowest value and the standard deviation  
345 more than doubled over the same time period. Off-peak electricity forward prices  
346 exhibit an even more dramatic increase in uncertainty, as evident from Figure 9.  
347 The average off-peak electricity forward price increased by \$8.34/MWh from  
348 January 2003 to January 2009, while the difference between the highest and  
349 lowest value almost tripled and the standard deviation more than doubled over the

350 same time period. Again, this increased volatility of forward prices means that the  
351 forecasted NSR could vary significantly simply by using alternative trading dates  
352 for the reference forward contracts. Projected gas expenses will also vary with the  
353 timing of the forecast, since gas dispatches in a manner that depends partly on the  
354 electricity market price curve.

Figure 8

Average, Min and Max of Peak 12-Month Forward Strip for Palo Verde  
(6-Month Ahead Delivery)

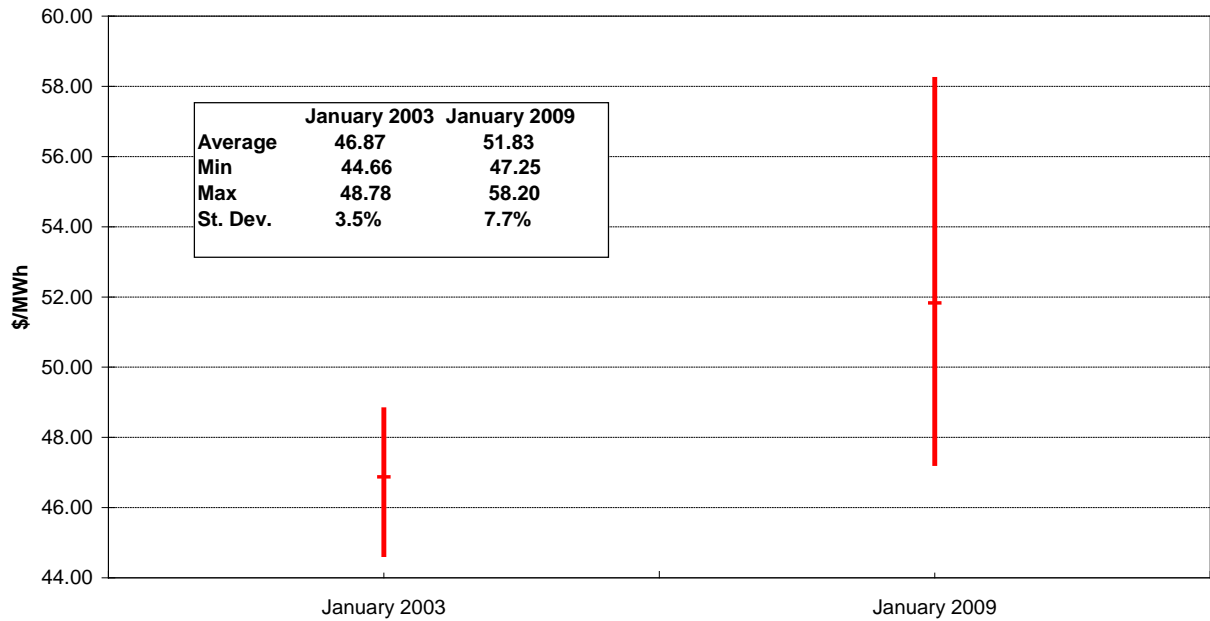

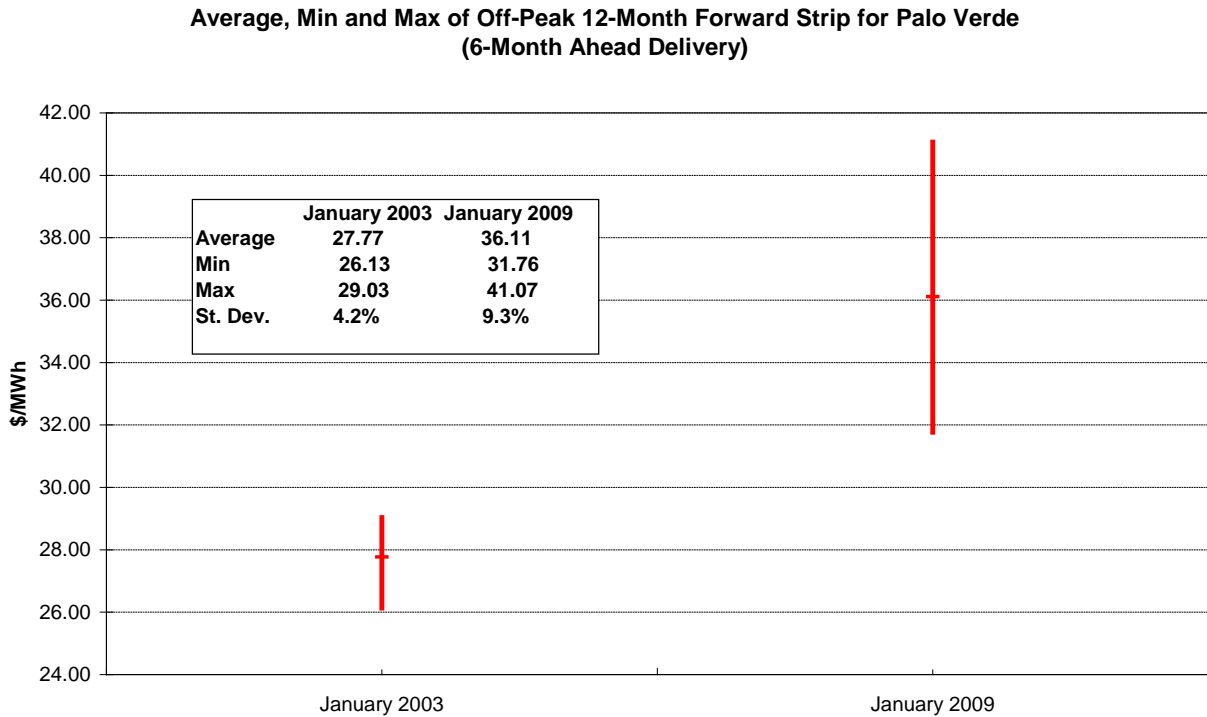

Figure 9

355 **Q. How would these views of market price volatility have compared to the**  
356 **outlook for gas and power market volatility prevailing or expected at the**  
357 **time the EBA was eliminated?**

358 **A.** The petition to cancel the EBA was filed in December 1990. At that time, the U.S.  
359 natural gas industry was experiencing a substantial, prolonged period of excess  
360 supply, and still displacing long-term take- or-pay gas with deep supplies of spot  
361 gas (induced by the 1978 Natural Gas Policy Act that gradually deregulated  
362 wellhead gas by 1985). By 1990, gas prices had been around \$2/Mcf for a few  
363 years and were expected to stay near that level for several years (as they actually  
364 did until about 1997). Relatedly, the electric industry had an excess supply of  
365 generation capacity, due to a combination of large baseload plants that had been  
366 built ahead of loads, and the surge of mostly gas-fired, baseload “qualifying

367 facilities” or QFs that were developed in response to PURPA. Wholesale  
368 restructuring of the electric industry had just occurred in England, but it was only  
369 a concept being debated for the U.S. among economists and some policy-makers  
370 at the FERC. It was not implemented until Order 888 in 1996 made open-access  
371 transmission a national requirement. Large-scale competition in wholesale power  
372 markets, with unregulated pricing by merchant generators, was not the norm until  
373 around 2000 when FERC Order 2000 fostered Independent System Operators  
374 (ISOs) and Regional Transmission Organizations (RTOs).

375 In short, both power and gas markets looked very different in 1990 than today.  
376 Forward contracts for gas and electricity comparable to those whose prices were  
377 shown above were not available for several more years, and spot markets were  
378 thin and far less volatile than what we have observed over the past decade.  
379 “System lambda” (i.e., the time pattern of hourly short run marginal costs of  
380 dispatching a specific utility’s generation fleet) was the reference point for power  
381 supply planning. Very few economists in 1990 would have offered a vision of the  
382 complex situation that RMP now faces. To the extent electricity competition was  
383 envisioned at all, the (now somewhat naïve) hope and expectation was that prices  
384 would become lower and less volatile for customers. Low-cost, natural gas-fired  
385 generation would supplant the lumpy, often expensive baseload capacity choices  
386 made in the past under regulation, and power plant owners rather than customers  
387 would bear the value and performance risk of those choices.

388 Unfortunately, the market realization has not always lived up to those  
389 expectations, with much more complicated markets for transmission and ancillary

390 services, occasional market power abuses, dramatically increased spot energy  
391 volatility, boom-bust cycles, and other complications. While it may have seemed  
392 plausible to abandon the EBA in 1990, the reasons and market circumstances  
393 supporting that change no longer apply.

394 **Q. Will variances between forecasts and actuals among factor inputs tend to**  
395 **offset each other?**

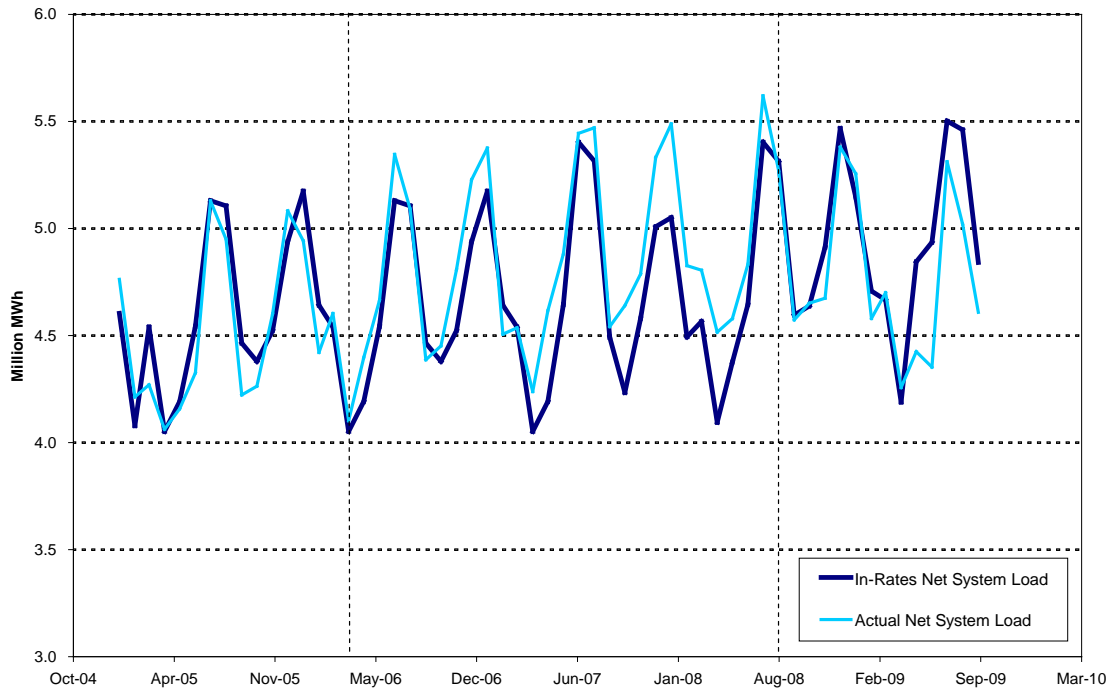

396 A. Not necessarily. Most of the very short-term, hourly or day-to-day variation in  
397 market conditions will tend to have positive and negative signs, but even those  
398 movements will not necessarily be offsetting. As I explained on pages 39-40 of  
399 my supplemental direct testimony, there tends to be a positive correlation between  
400 variances in forecasted quantities and spot gas or purchased power costs. For  
401 instance, if the actual load turns out to be higher than forecasted, a utility will  
402 need to cover the shortage through spot market purchases (either of power or of  
403 natural gas if its gas-fired power plants are available to generate at above-  
404 forecasted levels). When loads are high for RMP, they are likely to be high for  
405 neighboring utilities as well, so available supply is likely to be tighter and more  
406 costly. Thus supplemental purchases will often occur at higher prices than were  
407 originally forecast or locked in for the rest of the portfolio. Due to this positive  
408 correlation between variances in load forecasting and forecasted gas or purchased  
409 power prices, it is not necessarily the case that changes in forward demand  
410 forecast and gas and purchased power costs, which are the key input factors, will  
411 be offsetting.

412 **Q. Can variances between forecasts and actuals in factor inputs persist over**  
413 **time?**

414 A. Yes, a more serious problem than correlated short-term, unexpected movements  
415 in load and prices is long-term persistence in variances caused by systematic  
416 changes in market conditions and structure (e.g., drought, or changes in OPEC  
417 pricing, etc.). For example, a persistent under-estimation of net system load is  
418 evident in Figure 10 below, where the actual net system load is consistently above  
419 the forecasted (in-rates) net system load for over two years from March 2006 to  
420 late 2008. Also, systematic factors can combine to make a persistent variance in  
421 one factor also more costly than would have been expected. Higher than expected  
422 loads may occur if a year is abnormally warm at times when air conditioning is  
423 desired. But if such a year is also a drought year, then there may be a need for  
424 more gas generation than had been budgeted, and/or higher costs of net purchases  
425 (and more of them, to offset the lost hydro).

426 **III. INCENTIVES TO OPERATE EFFICIENTLY WILL NOT BE LOST**  
 427 **UNDER ECAM.**

428 **Q. Several intervener witnesses have expressed concerns that the ECAM will**  
 429 **undermine incentives for RMP to be careful in its power and fuel**  
 430 **procurement. Do you agree?**

431 **A.** I am aware of these concerns. In particular, Mr. Chernick suggests that an ECAM  
 432 will reduce RMP’s incentive to control costs “by reducing attention to the least-  
 433 cost procurement of gas and electric power, the marketing of wholesale power,  
 434 and maintaining and improving the fuel efficiency and reliability of generation,”<sup>6</sup>  
 435 while Ms. Michele Beck expresses concern about potential incentive problems

<sup>6</sup> Direct Testimony of Paul Chernick, p. 41 (lines 977-980).

436 inherent in ECAM-like mechanisms.<sup>7</sup> In theory, these concerns have some  
437 validity. However, I believe they are mistaken for three reasons: First, it is not the  
438 case that the existing system is perfect in every way with regard to incentives.  
439 Second, the new incentives feared under the ECAM, though perhaps present to  
440 some extent, are not likely to be very strong, nor is there any value to RMP from  
441 pursuing them. Third, if such issues are present, they can be addressed readily by  
442 new regulatory reporting and review, without any administrative difficulty.

443 **Q. Please elaborate on each of these, beginning with how the existing system**  
444 **may include some incentives that are also not necessarily ideal.**

445 A. The existing system involves reviewing all utility cost items concurrently at *ad*  
446 *hoc* intervals, and relying on occasional, possibly frequent, updates to fuel and  
447 power market forecasts in order to adjust rates (but not to true-up for any past  
448 over- or under-recovery of operating costs).

449 This no-ECAM approach implicitly encourages a utility to favor, utility-owned  
450 assets or fixed-cost supply contracts over resources and procurement strategies  
451 with more variable costs, even if the latter might be less expensive, on average.

452 This incentive arises because the utility is exposed to risks from fuel and short  
453 term power costs that are quite volatile, difficult to forecast, and largely  
454 uncontrollable. There is less risk and more financial certainty from assets put into  
455 ratebase with an allowed return, compared to operating costs that must be  
456 forecasted, with inevitable variances from forecasts (often large, as was

---

<sup>7</sup> Direct Testimony of Michele Beck, p. 16 (lines 338-341).

457 demonstrated in section I of this rebuttal testimony).<sup>8 9</sup> This bias towards lower  
458 risk assets that results from the lack of an ECAM is different than the bias  
459 sometimes noted for utilities of increasing the investment in rate-based assets. The  
460 former is just related to moving toward safer assets to avoid riskier fuel  
461 procurement while the latter is to increase earned returns.

462 In addition, the no true-up aspect of the current approach means that customers  
463 are at risk for paying amounts considerably different than actual costs. For the  
464 past several years, this has tended to occur in customers' favor, but there is no  
465 reason to believe that will be systematically true. Indeed, if it were systematically  
466 true, it would be evidence of a bias in the way forecasts are being made or set,  
467 which the utility should be entitled to correct.

468 **Q. Why aren't the new, adverse incentives interveners are worried about under**  
469 **the ECAM likely to be very strong?**

470 A. All that is really being alleged here is that the utility could become indifferent to  
471 the cost or risk of its fuel mix, not that it obtains a new, positive incentive to let  
472 costs rise or become more volatile. Since the utility will not enjoy any higher or  
473 different profits under the ECAM, regardless of whether fuel and power costs are  
474 high or low, there is no such positive incentive to let costs wander. This is just a  
475 fear of negligence creeping into utility operations, and that fear is totally

---

<sup>8</sup> If the utility is not earning an adequate return on equity, then there is also a disincentive to invest. This leaves the utility trying to choose the lesser of two fiduciary evils. This is very undesirable for its customers over the long run, because it means that resource adequacy and performance may become worse, and the utility is being forced to use decision criteria that are clearly not socially optimal.

<sup>9</sup> This is only true up to a certain point. Once a utility has enough owned assets that it is often a net seller of energy (or capacity), further fixed assets mostly bear spot market risk and so may not dampen overall volatility.

476 unfounded and naïve.  
477 Utilities recover a significant part of their fixed, non-ECAM costs through  
478 variable charges. For instance, a typical residential customer pays a small monthly  
479 customer charge and buys the rest of its utility service on a cents per kWh basis,  
480 even though many of the transmission, distribution and administrative costs are  
481 fixed. Thus, a utility's financial health is dependent on the volume of power sold,  
482 regardless of whether it has an ECAM or not. At some point, increased  
483 commodity costs under the ECAM will start to reduce consumption, so the utility  
484 retains a strong incentive to keep operating costs under control in order to protect  
485 its other cost-recovery.

486 Even absent fixed costs in variable charges, utilities depend heavily on overall  
487 customer satisfaction in order to achieve reasonable regulatory allowances for all  
488 of their costs. If they were to become indifferent to the pattern of fuel costs, it  
489 would eventually hurt their credibility with customers and redound adversely to  
490 their interests in subsequent rate cases. Beyond this latent risk, there are many  
491 more short-term, explicit incentives and constraints in place that create pressure  
492 and rewards for controlling costs, including executive performance evaluations  
493 and oversight responsibilities, operating budgets set annually, regulatory reviews  
494 and comparisons to other utilities' plants and rates, and the like.

495 **Q. If any such adverse incentives exist and are a material concern to regulators,**  
496 **can they be readily mitigated?**

497 A. Yes, these problems, though likely to be quite small already, are readily blocked  
498 with simple and useful regulatory oversight of integrated resource planning (IRP),

499 the ECAM costs and associated quality of service. Regulatory oversight of the  
500 IRP process should result in an optimal mix of long-term resources. Since  
501 operating costs are largely uncontrollable in-between times when the mix of fixed,  
502 long-term resources is altered (e.g., in an IRP process), the proper regulatory issue  
503 ought to be how the riskiness of these costs can be kept under control (not  
504 whether the costs should have been lower or higher on average). The efforts to  
505 control risk can be audited readily from reports on hedging practices (e.g, actual  
506 procurement vs. stated goals for hedging targets as to type, timing and quantities  
507 of hedges desired) and hedging success (as measured by forward-looking metrics  
508 of potential cost-risk staying within target ranges). These can be reported on as a  
509 routine aspect of ECAM filings providing assurance that no adverse choices are  
510 being made.

511 If there is a concern that RMP might be letting operating practices (such as  
512 maintenance) slide because any loss of efficiency (e.g., worse heat rates or  
513 availability) would just “flow through” the ECAM, then specific metrics of plant  
514 performance can be reviewed to see if they have slipped from historical or  
515 industry norms. Incentive terms can be created for these factors as well. It is very  
516 doubtful that that would prove necessary, but it would be simple to implement if  
517 needed.

518 **Q. Are there advantages to going to the ECAM approach, above and beyond the**  
519 **improvement in cost recovery reliability for RMP and the accurate collection**  
520 **of true costs from customers?**

521 A. Yes, the ECAM will replace the obsolete model of regulatory review and price-

522 setting that RMP is operating under now. Virtually every state in the country has  
523 adopted a policy of recognizing that the process, time frames, and standards for  
524 regulatory scrutiny of operating costs are different than the process, time frames,  
525 and standards for review of long-term resource mix decisions. This results in a  
526 more efficient and effective regulatory process for both.

527 Instituting an ECAM will allow for this kind of clear separation between fuel  
528 procurement and asset mix decisions. The kinds of costs falling under the ECAM  
529 are largely uncontrollable between resource mix decisions, except insofar as they  
530 can be substantially but not completely hedged. Hedging involves analytic tools  
531 for forecasting and measuring risk over a few-year horizon, and these tools are  
532 very different from those used in finding least-cost, long term choices. The  
533 performance metrics for risk management are focused on how well the managers  
534 have adhered to risk targets and risk control guidelines. These goals can be  
535 reviewed periodically as an input to the ECAM process, and then the routine  
536 review process can focus on their attainment.

537 This separation allows a much more efficient attention to the more controllable  
538 decisions a utility can make about its long term resource mix, which can be  
539 addressed in IRPs and base rate cases rather than the ECAM proceedings.

540 **IV. IMPLEMENTATION OF ECAM DOES NOT REQUIRE OR JUSTIFY A**  
541 **REDUCED COST OF CAPITAL**

542 **Q. Is cost of capital under an ECAM an appropriate concern for a Phase I**  
543 **review of whether the mechanism is in the public interest?**

544 A. No, I do not believe it is. The economic issue in this case ought to be how the

545 NPC risks facing RMP have increased over time, how readily they can be  
546 controlled (or not) and how that risk affects its ongoing financial health and ease  
547 of providing high quality service. The cost of capital question would normally be  
548 debated in base rate cases, rather than fuel cost-recovery analyses. However, a  
549 few intervenors have suggested that there is or should be some direct relation  
550 between the ECAM and the cost of capital,<sup>10</sup> which I believe is incorrect for  
551 reasons I will explain briefly here.

552 **Q. Why do you think there is no need to adjust, or even to plan to adjust, the**  
553 **cost of capital in conjunction with approving an ECAM?**

554 A. Despite the fact that an ECAM changes the way fuel and short term power costs  
555 are collected, there is no theoretical or empirical basis for concluding that an  
556 adjustment to the cost of capital is required, or if it were, for estimating *a priori*  
557 how much of an adjustment would be relevant. It is possible that the ECAM could  
558 eventually yield the benefit of lowering the cost of capital (especially for the debt  
559 portion), but any adjustment should wait until that effect is actually observed in  
560 the financial market data.

561 **Q. Isn't it true that the ECAM will reduce risk for PacifiCorp shareholders and**  
562 **therefore raise it for RMP customers?**

563 A. No, that cannot be concluded. The existing system based on forecasted costs,  
564 when a large portion of costs is not hedgeable or readily forecasted with material  
565 accuracy, simply results in a large forecasting risk that is borne by both  
566 shareholders and ratepayers. (That is, the variance from forecast could favor

---

<sup>10</sup> Direct Testimony of Mr. Chernick, p. 34 (lines 813-816) and Direct Testimony of Mr. Chriss, p. 13 (lines 5-12).

567 either one of the two groups.) There is no reason to believe that the rates under an  
568 ECAM will be systematically higher or lower, or more or less variable over  
569 annual periods, than has been experienced in the past. They will simply be more  
570 accurate reflections of truly incurred costs. In that sense, an ECAM may involve  
571 less cash-flow variance for RMP, but this will not necessarily reduce RMP's costs  
572 of funds. In particular, it is unlikely that the cost of equity will decline, because  
573 the cost of equity reflects market-correlated, undiversifiable or "systematic" risk,  
574 which may not describe the changes in cash flows under an ECAM.

575 • The forecasting risk that is reduced or eliminated with an ECAM may not be  
576 systematic at all, as there is no reason (or evidence) to believe that these variances  
577 from forecasts tend to be high when financial markets are booming and low when  
578 they are soft.

579 • Fuel price risk by itself (ignoring volume uncertainties) may also not be  
580 systematic, or may not be systematic to the same extent over time: Sometimes,  
581 fuel prices rise in a booming market with a strong economy. However, sharply  
582 rising fuel prices can also cause the economy to slow down. Perhaps because of  
583 this complexity, none of the intervenors suggesting a cost of capital adjustment  
584 has an objective, rigorous theory of how much adjustment might be required, just  
585 an informal sense (or desire) for some kind of offset.

586 • The cost of equity is typically estimated from the returns earned or required by a  
587 group of similar, "proxy" firms – in this case other utilities. But in the U.S.,  
588 essentially all of those utilities will already have an ECAM-like cost recovery  
589 mechanism for their fuel and purchased power costs, so any risk-reduction  
590 benefits that arise from such mechanisms is already in the proxy data.

591 **Q. What about the cost of debt? Is it also unlikely to be affected by the ECAM?**

592 A. It is more plausible that the cost of debt might fall, eventually, due to the ECAM,  
593 because the risk premium in debt (above the yield on government bonds of similar  
594 maturity and tax structure) is largely due to potential default risk, which in turn  
595 depends on total risk more than on systematic risk. The ECAM will reduce total  
596 risk to lenders, and so may result in lower borrowing rates. However, this will not

597 affect the embedded cost of debt, only the future cost of additional debt. That  
598 effect can be rolled into rates if/when it happens.

599 **V. CUSTOMER INVOLVEMENT ON HEDGING GOALS SHOULD NOT**  
600 **DELAY APPROVAL OF THE ECAM APPROACH.**

601 **Q. Witness Ms. Beck has suggested that the ECAM should be suspended until**  
602 **there can be more customer involvement in setting the goals and parameters**  
603 **of the hedging that the Company can pursue to manage risks. What role do**  
604 **you believe there is for such customer input?**

605 A. It is certainly true that the hedging practices behind the ECAM should be  
606 designed with consideration of what types of risk are tolerable to customers.  
607 However, there is no reason to delay the ECAM for review of this question, for  
608 several reasons. First, customers do not yet have any experience with the pattern  
609 of costs that will come out of the ECAM as proposed, so they have no strong  
610 basis for saying what alternative pattern of risk exposure they might prefer.  
611 Second, it is likely that there is no universally acceptable or preferred pattern of  
612 NPC risk that will satisfy all or even most customers simultaneously. Third, there  
613 are limits and tradeoffs on how much risk can be reduced, and these may not yet  
614 be familiar to intervenors representing customers, nor to regulators. That  
615 familiarity will develop through review of the ECAM performance under existing  
616 hedging practices.

617 Thus it will take some time and experience with the ECAM before it is known  
618 whether the hedging risk goals should be revised to better match customer  
619 preferences. Meanwhile, there is no reason to believe that the existing hedging

620 practices are not relevant or sufficient as a starting point. Once an ECAM is  
621 approved, the Phase II process of developing its implementation plan can include  
622 some discussion of what kinds of performance reports and benchmarks should be  
623 tracked. Over time, these can be used, along with customer reactions, to decide if  
624 the goals should be modified to pursue some other pattern of potential risk  
625 exposure.

626 Indeed, much of the way the ECAM risks ultimately will be felt by customers  
627 does not even depend on how the Company hedges its procurement, but on how it  
628 recovers the variances in rates over time. This is also a Phase II issue that can be  
629 discussed in concert with other policy questions, such as how much pricing  
630 efficiency is desired in the new structure.

## 631 **VI. CONCLUSIONS**

632 **Q. Please summarize your rebuttal conclusions.**

633 A. Accurate cost recovery for fuel and purchased power are critical to ensuring the  
634 financial health of any utility. This is especially true when the utility is embarking  
635 on a sustained capital expenditure program requiring significant cash flow for  
636 investment, in a tight credit market. (See the supplemental direct testimony of  
637 RMP witness Mr. Bruce Williams in regard to the planned expenditures.) The  
638 difficulty in accomplishing that with the existing approach in Utah has increased,  
639 and this situation is not amenable to fixing with better forecasting or hedging.  
640 There is large, but reasonable exposure to variances from the substantial amount  
641 of short term market balancing that is required to serve loads with the PacifiCorp  
642 resources. These difficulties are likely to increase in the future, as more and more

643 nonstandard (renewable) resources are added to the system and the regional grid,  
644 and as climate policy constraints become part of the power market environment.  
645 Thus, it is timely to introduce an ECAM now, and to tune it up over time after a  
646 meaningful history of performance reporting is in hand.

647 In general, it is harder to restore financial credibility than to preserve it. An  
648 ECAM can help preserve financial health for RMP and PacifiCorp, thereby  
649 making its future capital requirements for system maintenance and improvements  
650 easier to achieve at reasonable financial cost. This will benefit customers, as will  
651 having a cost recovery mechanism that reliably recovers only the actual operating  
652 costs of RMP. The ECAM process will also prove to be a regulatory benefit,  
653 efficiently separating the review of non-controllable operating costs from longer  
654 term resource and risk-measurement

655 **Q. Does this conclude your testimony?**

656 A. Yes it does.
