COST OF SERVICE
(NET METERING PROGRAM)

DIRECT TESTIMONY OF STAN FARYNIARZ
ON BEHALF OF
THE UTAH DIVISION OF PUBLIC UTILITIES

June 8, 2017

1 **I. INTRODUCTION**

2 **Q. What is your name and business address?**

3 A. My name is Stan Faryniarz. I work for Daymark Energy Advisors (“Daymark”),
4 headquartered at One Washington Mall, 9th Floor, Boston, MA 02108.

5

6 **Q. On whose behalf are you testifying in this proceeding?**

7 A. I am testifying on behalf of the Utah Division of Public Utilities (“Division” or “DPU”).

8

9 **Q. Have you testified before the Utah Public Service Commission previously?**

10 A. Yes, in Docket 13-035-184, which addressed Rocky Mountain Power’s general rate case
11 and rate design issues, RMP’s net energy metering (“NEM”) program, and its proposed
12 facilities charge for NEM customers.

13

14 **Q. Please describe your background and experience.**

15 A. I am a Principal Consultant at Daymark. I am an energy economist and power supply
16 planning and management specialist with 31 years of experience in areas including
17 electric utility cost of service and rates, power supply procurement and management,
18 wholesale and retail power transactions, power project financial analysis and due
19 diligence, asset and utility valuations, and integrated resource planning and analysis.

20

21 I have advised managers concerning the electric power supplies of public and investor-
22 owned electric utilities, and have advised large industrial customers, regulators, consumer

23 advocates, and power plant developers and owners regarding specific power projects and
24 transactions, portfolio risk management strategies, and power markets.

25
26 I have prepared numerous valuation analyses of power projects and assets, combined
27 portfolios of assets, and electric utilities. This work has involved power production
28 assets in the northeastern U.S., North Carolina, Ohio, Arkansas, Wisconsin, and Canada.

29 I have evaluated the economics, contract structure, ratepayer security, development
30 prospects or going-forward value of dozens of renewable, non-renewable merchant, and
31 Qualifying Facility (“QF”) power projects in the northeastern U.S. and Canada. I have
32 conducted this work for regulators and for providers of private capital and quasi-public
33 capital.

34
35 I have prepared, or have overseen the preparation of all or portions of integrated resource
36 plans for several Vermont utilities and for other public utilities, and I am a load
37 forecasting specialist.

38
39 My experience includes the preparation of well over a dozen electric and water utility
40 allocated cost of service and rate design studies, rate unbundling studies, and rate path
41 projection studies, for or involving utilities in the northeastern U.S., North Carolina, and
42 New Hampshire.

43

44 My experience and qualifications are described in more detail in my resume and selected
45 testimony appendix, which are attached as DPU Exhibit 2.1 DIR-COS.

46

47 **Q. Please describe your educational background.**

48 A. I have a bachelor's degree with honors in Economics, and a Master's degree in Public
49 Administration (finance and managerial economics concentration) from the University of
50 Vermont. I have completed additional post-graduate coursework in Regulatory
51 Economics, and I hold the Certified Energy Procurement (CEP) Professional credential
52 from the Association of Energy Engineers.

53

54 **Q. What is the purpose of your testimony?**

55 A. I have been retained by the Division to review and analyze the cost of service studies,
56 load research study, distribution level costs and benefits of distributed generation ("DG"),
57 and other aspects of the net metering program that were presented by Rocky Mountain
58 Power ("RMP", "PacifiCorp", or "the Company") in its Compliance Filing.

59

60 **Q. What material did you review before you prepared your testimony?**

61 A. I began with an analysis of the Company's NEM rate design proposal, as outlined in
62 testimony provided by RMP. I reviewed direct testimony, which included the
63 Company's NEM rate design proposal provided by the Company's five witnesses, and
64 various data requests and responses in this docket. I have also reviewed certain materials

65 associated with other Public Service Commission of Utah (“Commission”) proceedings
66 that are relevant to this one.

67

68 **Q. What areas will your testimony address?**

69 A. I will address the following:

- 70 • The reasonableness of the Company’s Actual Cost of Service (“ACOS”),
71 Counterfactual Cost of Service (“CFCOS”), and Net Energy Metering
72 Breakout Cost of Service (“NEM Breakout COS”) studies.
- 73 • The results of RMP’s load research study.
- 74 • A review of the Company’s proposed distribution level costs and benefits
75 associated with distributed generation on its system.
- 76 • The appropriateness of the Company’s proposal to separate NEM customers
77 into their own class.
- 78 • The appropriateness of the Company’s proposed Schedule 5 rate design,
79 which includes demand charges and an increased customer charge, and related
80 public policy issues.
- 81 • The current compensation for excess generation from residential customers.
- 82 • The Company’s proposal to eliminate the option to receive excess generation
83 compensation at the average retail rate for non-residential customers.
- 84 • The Company’s proposal to implement new application fees for all levels of
85 requests for interconnection.
- 86 • Other miscellaneous issues.

87

88 **Q. Please summarize your conclusions and recommendations.**

89 A. My conclusions and recommendations include:

- 90
- 91 • Based on my analysis and findings described below, it is not necessary, for now
92 and at the current level of penetration, to separate NEM customers into their own
93 class. Despite this, I do not object to the separation of NEM customers into a
94 separate class if deemed appropriate for other policy reasons, or to address
95 compensation rates for excess generation exported to the grid.
 - 96 • My conclusions regarding the importance of correctly valuing exports, NEM costs
97 and benefits, and the use of application fees and interconnection fees apply to
98 both residential and commercial NEM customers.
 - 99 • Compensation for energy exports at retail rates is the primary driver of the low
100 revenue parity ratio for residential NEM customers shown in the Company's
101 NEM Breakout ACOS study.
 - 102 • Traditional NEM excess energy compensation, at full retail rates, is not
103 sustainable in the long-run with very high rates of DG penetration.
 - 104 • Since the Company is using a one-year historic test-period for its cost-benefit
105 analyses as discussed from the Phase I Commission Order, it is likely that
106 transmission, distribution, and environmental compliance avoided cost benefits
107 may not be able to be properly captured. Evidence of such benefits might be
108 presented by other parties in this docket and I will respond subsequently as
appropriate.

- 109
- I would recommend that the Commission consider opening a separate docket to
110 properly vet possible DG costs and benefits to RMP's distribution system, which
111 potentially could include parties to the current docket and all stakeholders with an
112 interest in DG, in order to determine the export compensation rate.
 - I agree with the Company that there is a cost of interconnection incurred for both
113 program administration and engineering review when a customer submits an
114 interconnection application for any DG system, regardless of size. These costs
115 should be borne only by the applicants since non-NEM customers are not
116 contributing to these costs. In addition, I recommend that interconnection costs
117 vary based on whether the interconnecting DG system is expected to export power
118 to the grid.
 - I recommend the Company clarify how the need to meter bidirectional flows
120 would impact average per meter costs to serve Schedule 23 NEM customers
121 compared to non-NEM customers.
 - I do not recommend that transformer costs be included in the customer charge for
123 residential customers. Although these costs may be fixed, that does not by itself
124 justify their inclusion in the customer charge. In addition, any transformer
125 upgrades needed are best recovered through an interconnection charge and not a
126 monthly customer charge.
 - I recommend the Company ensure that the transformer allocator does not double
128 count customers in its NCP calculation. This should reduce costs allocated to the
129 NEM residential class for the NEM breakout ACOS study.
- 130

- 131 • Regardless of the ultimate rate design and rates approved by the Commission, the
132 rate design and rates should be gradually implemented through steps that enable
133 proper transition to bi-directional meters and avoid or mitigate adverse average
134 rate and bill impacts for customers.
- 135 • Data collection through a rate pilot program(s) could enable the Commission to
136 make more informed decisions about different time-based rate structures going
137 forward.
- 138 • By decreasing the NEM program cap to a level near the current program size or a
139 near-term projection of size, the Commission can create a defensible class of
140 NEM customers that might be gradually transitioned while newcomers after the
141 Commission's order in this proceeding might have a new regime immediately
142 applied.

143

144 **II. BACKGROUND**

145 **A. Net Metering History**

146 **Q. Please briefly describe Utah's Net Metering Statute history.**

147 A. In 2002, the Net Metering Statute (Utah Code Ann. § 54-15-101 et seq.) was enacted. On
148 May 13, 2014, a revision to the Net Metering Statute, addressing the determination of
149 cost and benefits, became effective. Utah Code Ann. § 54-15-105.1 requires the
150 Commission to:

151 (1) determine, after appropriate notice and opportunity for public comment,
152 whether costs that the electrical corporation or other customers will incur from a
153 net metering program will exceed the benefits of the net metering program, or
154 whether the benefits of the net metering program will exceed the costs; and

155 (2) determine a just and reasonable charge, credit, or ratemaking structure,
156 including new or existing tariffs, in light of the costs and benefits.

157 For the remainder of my testimony, I will refer to Utah Code Ann. § 54-15-105.1(1) as
158 Subsection One and Utah Code Ann. § 54-15-105.1(2) as Subsection Two.

159

160 **Q. What other legislation is impacting net metering in Utah?**

161 A. In addition to the Net Metering Statute, on March 25, 2014, the Legislature signed Senate
162 Bill 208 into law, which required the Commission to “convene a process to evaluate the
163 costs and benefits of net metering, and to determine a “just and reasonable” rate structure
164 considering those costs and benefits”¹. The Commission initially opened this docket
165 back on August 29, 2014 to review RMP’s net metering program costs and benefits, as
166 required by Subsection One.

167

168 **Q. What did the Commission order in the docket?**

169 A. On November 10, 2015, the Commission ordered RMP to make a Compliance Filing²
170 that consists of two COS studies (ACOS and CFCOS) covering the test period used in
171 RMP’s next general rate case. These COS studies would serve as a framework to assess
172 the costs and benefits of net metering by comparing a COS study without net metering
173 customers to a COS study with net metering customers. The Commission order
174 specifically stated³:

¹ <http://programs.dsireusa.org/system/program/detail/743>.

² I use the term Compliance Filing here as a label for what the Commission required in its order, not in reference to the Company’s filing, which it also termed a “Compliance Filing”, and which differs from the Commission’s order in certain respects. Despite the difference, I will refer to the Company’s filing as its Compliance Filing for convenience.

³ Docket No. 14-035-114 Order, November 10, 2015, p. 16.

- 175 1. Two cost of service studies as described in this order. In one cost of service
176 study (the “CFCOS”), PacifiCorp will use its best efforts to estimate what its cost
177 of service would be if net metering customers produced no electricity, drawing
178 their entire load from PacifiCorp and providing no surplus energy to the system.
179 The second cost of service study (the “ACOS”) should reflect PacifiCorp’s actual
180 cost of service with net metering customers’ participation, meaning PacifiCorp
181 provides net metering customers with energy only when their self-generation is
182 insufficient to meet their load and net metering customers push any surplus
183 energy they produce to the system.
184
- 185 2. Both the CFCOS and ACOS will reflect costs at the system, state and customer
186 class level.
187
- 188 3. The ACOS will illustrate cost of service in two respects at the customer class
189 level. First, the ACOS will reflect class cost of service with net metering
190 customers included in their existing class. Second, the ACOS will segregate net
191 metering customers from the class in which they presently participate and reflect
192 the resulting class cost of service to the net metering customers as a separate class
193 and show the impact their segregation has on the class in which they would
194 otherwise participate.
195
- 196 4. The period of time covered by each of the cost of service studies shall be
197 commensurate with the test period in PacifiCorp’s next general rate case.
198

199 **B. RMP’s Compliance Filing**

200 **Q. Please briefly explain the COS studies the Company provided as part of its**
201 **Compliance Filing.**

202 A. After the Commission’s order, the Company filed an ACOS study and a CFCOS study
203 that compared the costs of service at the system, state, and customer class levels. For both
204 COS studies, the Company used a one-year test period, which ended December 31, 2015,
205 and modeled the costs to serve customers in its jurisdictional allocation model (“JAM”).
206 The COS studies were supported by a load research study, which compiled a year’s worth

207 of data for all customers, including data for residential NEM customers, but not NEM
208 customers on Schedules 6, 10, and 23.⁴

209
210 In addition to the ACOS and CFCOS, the Commission required the Company to
211 complete a NEM Breakout COS, which placed net energy metering (“NEM”) customers
212 into a separate class to show how their removal affected the class they otherwise
213 belonged under. The NEM Breakout COS was created by taking the ACOS study and
214 separating out NEM customers from each of the classes (residential, Schedule 23,
215 Schedule 6, Schedule 8, and Schedule 10) based on their cost of service characteristics.

216

217 **Q. What are the differences between the ACOS and CFCOS studies?**

218 A. The main difference between the two COS studies was that the CFCOS study relied on
219 the Company’s estimation of the cost of serving the current NEM customers if they were
220 completely reliant on RMP for all their electricity needs, meaning they do not generate
221 any of their own requirements, nor do they export surplus energy to the system. By
222 assuming the NEM program no longer existed, the Company made the following
223 assumptions in its counterfactual JAM (“CFJAM”): higher net power costs (“NPC”) to
224 supply energy⁵ and to account for line losses for remote energy delivery; removing bill
225 credits from private generation; lower costs for metering, customer service, billing, and
226 engineering and administrative interconnection costs; and allocating more system costs to

⁴ Direct Testimony of Robert M. Meredith, p. 25, lines 520-522.

⁵ To make up for energy not generated by NEM customers.

227 Utah because of increased energy demands in the state.⁶ The CFJAM is used in the
228 CFCOS, which includes higher revenues, energy, and demands for classes that include
229 NEM customers.⁷ In addition to these changes, the Company applied a \$2.0 million rate
230 decrease to the CFCOS results (difference between the CFJAM and ACOS JAM) to hold
231 the rate of return constant between the two COS studies.⁸

232

233 **Q. What assumptions did the Company make in the CFCOS regarding increased**
234 **energy consumption due to assumed lack of private distributed generation?**

235 A. The Company's ACOS uses the known amount of net energy usage and net revenue
236 associated with that usage that it bills to NEM customers. The Company's CFCOS
237 provides an estimate of the DG production to determine full requirements usage. DG
238 production is "estimated by multiplying a standardized production profile by the
239 nameplate capacity of each customer's generation system on a monthly basis".⁹ Then full
240 requirements usage can be determined by adding the estimated DG production less the
241 energy exported from the NEM customer to the grid plus the energy delivered to the
242 NEM customer from the grid.¹⁰ This is done for each class to get the total full
243 requirements energy for all NEM customers on the system.

244

⁶ Direct Testimony of Robert M. Meredith, pp. 4-5, lines 83-95.

⁷ *Id.*, p. 5, lines 99-100.

⁸ *Id.*, p. 5, lines 103-106.

⁹ *Id.*, p. 9, lines 176-178.

¹⁰ The energy flowing from the NEM customer to the grid and vice versa is measured using a bi-directional meter.

245 The standardized production profile used to estimate DG production was generated from
246 data gathered from 36 production profile meters capable of capturing 15-minute interval
247 data from willing residential customer participants in the Company's load research
248 study.¹¹ Specifically, the Company created generic shapes for all DG systems using the
249 production profile data collected by assigning the value of 1.0 to the highest 15-minute
250 reading and then dividing all other values by that reading. The overall standardized
251 production profile is the average of all the generic production shapes for the state,
252 weighted by the generic profiles of each county by total nameplate capacity installed in
253 each county through the end of 2015. The Company benchmarked its standardized
254 production profile against hourly shapes from the National Renewable Energy Laboratory
255 ("NREL") online PVWatts[®] calculator and found that they were similar.

256

257 **Q. Based on the energy sales assumptions the Company made in the CFCOS, how do**
258 **the energy sales in the CFCOS compare to the ACOS?**

259 A. The energy sales in the CFCOS are estimated to be 239,706 MWh, which is 51,297 MWh
260 more than the actual 2015 energy sales of 188,410 MWh.¹² This difference is 1,580
261 MWh less than the Company's estimated DG production of 52,877 MWh¹³ and is
262 explained to be caused by NEM banking¹⁴, which is reflected in the ACOS, but not the
263 CFCOS.

¹¹ Direct Testimony of Robert M. Meredith, p. 10, lines 183-186.

¹² *Id.*, p. 12, lines 227-230.

¹³ *Id.*, p. 12, lines 234-235.

¹⁴ Crediting of kWh from a current bill to a future bill due to delivering more energy to the grid than consuming from the grid in the current billing period.

264

265 **Q. What assumptions did the Company make in the CFCOS regarding increased**
266 **demand due to assumed lack of private distributed generation?**

267 A. At the input level, the Company modified Utah state border loads and allocation factors,
268 accounting for line losses, to adjust for the change in DG production that previously
269 reduced Utah's jurisdictional allocation.¹⁵ To be consistent with how loads were
270 developed in the CFJAM, customer class loads in the CFCOS were expanded by the total
271 DG production profile. In addition, the Company accounted for line losses by first
272 bringing DG production to the input level. This involved determining the monthly
273 installed capacity for customers served at both the primary and secondary voltage levels.
274 Then DG production was expanded by class by loss factor.¹⁶ So, with line losses now
275 incorporated, DG production at the input level increased by 4,907 MWh from the
276 estimated 52,877 MWh, reflecting 8% line losses.

277

278 **Q. What assumptions did the Company make in the CFCOS regarding bill credits?**

279 A. RMP removed bill credits¹⁷ from the CFCOS by putting the energy differences between
280 the full requirements and actual billed energy into summer and winter blocks, and when
281 possible, peak and off-peak periods, and multiplying the energy blocks by the revenue
282 differences.¹⁸ Because residential customers have tiered block usage levels, the Company
283 had to first estimate the full requirements energy for each monthly bill to determine levels

¹⁵ Direct Testimony of Robert M. Meredith, pp. 13-14, lines 255-262.

¹⁶ See 2015 cost of service study for loss factors used based on quantities of nameplate capacity.

¹⁷ See Exhibit RMP_(RMM-5) for bill credits by rate schedule.

¹⁸ Direct Testimony of Robert M. Meredith, p. 14, lines 277-281.

284 of energy consumption. Then the proportional changes in energy by tier were applied to
285 total estimated energy change to estimate the residential class' bill credits.¹⁹

286

287 **Q. What assumptions did the Company make in the CFCOS regarding customer**
288 **service and billing costs for NEM customers?**

289 A. Costs²⁰ for customer service and billing attributable to NEM customers were developed
290 by multiplying call center agent fully-loaded hourly costs by time estimates from
291 Company personnel involved in phone calls related to the NEM program, initial setup of
292 customers on the NEM program (including exchange of meters and billing system setup),
293 and ongoing support for NEM customers once they enroll in the program (including
294 billing back office support).²¹ To determine cost allocation by class for the period, each
295 activity's total costs were allocated based on cost drivers, i.e. phone calls were allocated
296 to application numbers, initial setup was allocated to interconnection requests, and
297 ongoing support was allocated to average bill numbers.²²

298

299 **Q. What assumptions did the Company make in the CFCOS regarding NEM program**
300 **administration?**

301 A. Since PacifiCorp has a NEM program administration department that processes
302 interconnection applications in six states, it allocated program administration costs²³ to

¹⁹ *Id.*, p. 15, lines 282-287.

²⁰ See Exhibit RMP_(RMM-6) for customer service and billing costs by class.

²¹ Direct Testimony of Robert M. Meredith, pp. 15-16, lines 295-306.

²² *Id.*, p. 16, lines 307-315.

²³ See Exhibit RMP_(RMM-7) for administrative expenses by class, state and rate schedule.

303 Utah based on the state's proportional workload, which was further reduced by
304 application fees the Company collected from larger commercial interconnections.²⁴

305

306 **Q. What assumptions did the Company make in the CFCOS regarding engineering**
307 **costs related to the NEM program?**

308 A. Similar to the customer service and billing cost allocation, the Company estimated
309 application review time and then multiplied it by a field engineer's fully-loaded hourly
310 cost and then by the total number of 2015 applications.²⁵ Engineering expenses for the
311 different rate schedules vary based on application complexity²⁶, which the Company
312 asserts leads to longer review time.

313

314 **Q. What assumptions did the Company make in the CFCOS regarding metering costs**
315 **related to the NEM program?**

316 A. Under the current NEM program, billing requires measuring the bi-directional energy
317 flow. Therefore, metering costs were estimated by the Company based on replacement
318 and reprogramming of current meters.²⁷

319

320 **Q. What were the results of the Company's ACOS and CFCOS analysis?**

²⁴ Direct Testimony of Robert M. Meredith, p. 16, lines 318-324.

²⁵ *Id.*, p. 17, lines 330-335.

²⁶ See Exhibit RMP_(RMM-8) for engineering expenses by customer class.

²⁷ See Exhibit RMP_(RMM-9) for metering costs by customer class and calculations showing meter depreciation and deferred tax impacts.

321 A. Per the Company’s analysis, the net metering program produced a *net cost* at the system,
322 state, and class levels. Specifically, the Company found that the net cost of the net
323 metering program was \$3.7 million (about \$70.40/MWh)²⁸ to the system, \$2.0 million
324 (about \$38.76/MWh) to the state, and \$1.7 million (about \$58.60/MWh) for the
325 residential class.²⁹ The Company provided the summary table shown below³⁰, which
326 shows the net cost of the net metering program at all levels, including a class level
327 impact.

328 **Table 1 – Net Cost/(Benefit) of the Net Metering Program at the System, State, and**
329 **Customer Class Levels.**

	Cost (000)	Benefit (000)	Net Cost/ (Benefit) (000)
System Level	\$ 5,010	\$ (1,287)	\$ 3,722
State Level	\$ 5,010	\$ (2,960)	\$ 2,049
Residential	\$ 3,540	\$ (1,881)	\$ 1,659
Schedule 23	\$ 504	\$ (405)	\$ 100
Schedule 6	\$ 673	\$ (650)	\$ 23
Schedule 8	\$ 240	\$ (395)	\$ (155)
Schedule 10	\$ 29	\$ (21)	\$ 7
Other Classes	\$ 22	\$ 393	\$ 415
Total Customer Class Level	\$ 5,009	\$ (2,960)	\$ 2,049

330
331
332 **Q. What other cost of service analysis did the Company perform in compliance with**
333 **the November 2015 Commission Order?**

²⁸ MWh is defined as megawatt hour.

²⁹ Direct Testimony of Robert M. Meredith, p. 6, lines 116-118, 122-123, and 127-129.

³⁰ *Id.*, p. 7, line 135

334 A. As I discussed earlier, the Company completed a NEM Breakout COS study to show the
335 cost to serve NEM customers from the ACOS if they were put into a separate class. The
336 costs to serve NEM customers are based on their characteristics, which include “different
337 customer counts, revenues, energy values, system coincident peak demand values,
338 distribution coincident peak demand values, non-coincident peak demand values, number
339 of customers per transformer, and metering costs.”³¹

340

341 **Q. Based on the different characteristics of NEM customers, how did the Company**
342 **develop demand values for NEM customers?**

343 A. When the Company conducted its load research study, it gathered 15-minute interval data
344 measuring delivered and exported energy for 36 residential NEM customers for 2015.³²
345 The Company developed loads for the NEM Breakout COS by using “delivered energy to
346 inform strata weightings and breakpoints, because delivered energy is an indication of the
347 customer’s usage of the system, as opposed to net energy that is a billing-related
348 construct”.³³

349

350 NEM customer profiles were scaled to monthly energy volumes, which allowed the
351 Company to develop monthly system and distribution coincident peaks based on energy
352 deliveries to the customer. Further, the Company averaged the non-coincident peaks for
353 each of the NEM sample customers and then scaled this value based on the total number

³¹ *Id.*, p. 19, lines 376-379.

³² However, the Company used data from 52 meters to develop loads for the NEM Breakout COS. Direct Testimony of Robert M. Meredith, p. 21, lines 418-420.

³³ Direct Testimony of Robert M. Meredith, p. 21, lines 427-430.

354 of customers to create a non-coincident monthly peak, which was based on the maximum
355 of energy delivered or exported.³⁴

356
357 The Company does not have separate data for NEM customers in Schedules 23, 6, and
358 10. So, full requirements profiles were created by adjusting the standard profile for each
359 class from the ACOS study “to the overall energy volume for estimated full requirements
360 usage of net metering customers on a monthly basis”.³⁵ Then the Company estimated
361 hourly delivered and exported energy by overlaying estimated DG production profiles for
362 each class. The Company noted that Schedule 8 customer demand values are determined
363 from profile meter readings for all customers.

364

365 **Q. Did the Company include any other differences in its NEM Breakout COS study?**

366 A. Yes. The Company assigned engineering, administration, customer service, and billing
367 costs that it claimed were attributable to NEM customers due to the interconnection
368 process and service needs of the NEM customers.³⁶ In addition, NEM customers can be
369 allocated energy costs the Company incurs to serve them, i.e. based on their usage of the
370 system, and can be credited for the excess generation they provide. This credit is assigned
371 to NEM customers “based upon differences in monthly net power costs associated with
372 private generation that was calculated for the CFCOS analysis”.³⁷ In addition, the
373 Company captures avoided line losses by increasing the credits that it applies to excess

³⁴ *Id.*, p. 19, lines 387-390.

³⁵ *Id.*, p. 20, lines 402-404.

³⁶ *Id.*, p. 21, lines 434-436.

³⁷ *Id.*, p. 23, lines 465-466.

374 generation delivered to the system. For the NEM Breakout COS, the Company also
375 considered the impact of banking because the cost of service study used billed energy
376 revenues from NEM customers that were impacted by banking outside of the test year.
377 The Company explains that “[s]ubtracting the excess energy, which includes both the
378 energy exported as well as the impact of banking, from the delivered energy, produces
379 the billed energy upon which revenues are determined and upon which the total energy in
380 the ACOS is based.”³⁸ By including impacts of banking, the Company claims it is
381 ensuring there is not a mismatch created between revenues and cost of service.

382

383 **Q. How does the Company allocate excess energy credits in the NEM Breakout COS?**

384 A. Excess generation credits are assigned to each NEM class, as well as an offsetting cost
385 for the excess generation credits that is based on Factor 30 - Energy, and are
386 functionalized in the Company’s Production function.³⁹ Offsetting costs were included in
387 the cost of service model to balance out direct assignment of excess credits to NEM
388 customers. The Company claims that “a fair value”⁴⁰ was given to the excess generation
389 credits in the NEM Breakout COS, which recognizes the benefits these credits provide to
390 the system, i.e. reduced net power costs. So, in the NEM Breakout COS, the Company
391 assigns offsetting cost for excess generation credits to all classes, both NEM and non-
392 NEM.

393

³⁸ *Id.*, p. 24, lines 486-489.

³⁹ *Id.*, p. 24, lines 492-495.

⁴⁰ *Id.*, p. 24, lines 498-500.

394 **Q. What other differences did the Company's NEM Breakout COS have to address?**

395 A. Like the other COS studies, the NEM Breakout COS study had to estimate the cost to
396 serve Schedule 6, 10, and 23 customers in separate classes because the load research
397 study did not have information for these customers as it did with the residential NEM
398 customers.

399

400 **Q. What were the results of the Company's NEM Breakout COS analysis?**

401 A. Per the Company's analysis, if NEM residential customers were separated into their own
402 class, non-NEM residential customers would incur \$1.1 million less in costs. However,
403 costs for non-NEM customers served under Schedules 6, 8, and 10 would increase by
404 \$0.3 million, \$0.2 million, and \$0.04 million, respectively.⁴¹ The Company claimed that
405 these increased costs are likely more due to the lower DG production from the Schedule
406 6, 8, and 10 customers compared to their full requirements energy usage. The Company's
407 main conclusion from this analysis was that residential NEM customers do not pay
408 enough to cover the Company's cost to serve them, which is significantly different than
409 serving other non-NEM residential customers.⁴² To further emphasize its point, the
410 Company provided a table showing revenue to cost of service parity ratios, which is
411 provided below.⁴³ The ratio identifies the percentage of the total allocated cost of service
412 of each class, actually paid by the relevant customer class. The highlight of the table is

⁴¹ *Id.*, p. 26, lines 545-546.

⁴² *Id.*, p. 27, lines 561-564.

⁴³ *Id.*, p. 28, line 575.

413 the 60.6% for residential NEM customers, which shows the revenues the Company
414 collects from them is not close to the cost the Company incurs to serve them.

415 **Table 2 – Revenue to Cost of Service Parity Ratios.**

	Parity to Cost of Service		
	ACOS	ACOS W/O	ACOS NEM
Residential	96.0%	96.1%	60.6%
Schedule 23	107.2%	107.3%	92.2%
Schedule 10	95.3%	95.1%	89.8%
Schedule 6	107.7%	107.7%	109.2%
Schedule 8	104.1%	104%	109%

416
417
418 The Company further compares the NEM Breakout COS to the ACOS and CFCOS and
419 finds that the NEM Breakout COS results shows that the residential NEM class revenues
420 collected would need to increase by \$1.8 million for the Company to earn the
421 jurisdictional average rate of return.⁴⁴ In addition, the Company adjusts the results of the
422 NEM Breakout COS to the same level of costs from its last general rate case (“2014
423 GRC”) to ensure the residential NEM class rates are set on the same basis as the rates for
424 all other customers.⁴⁵

425
426 **C. Load Research Study**

427 **Q. Please describe the Company’s load research study that it used for the cost of**
428 **service studies.**

⁴⁴ *Id.*, pp. 28-29, lines 582-583.

⁴⁵ *Id.*, p. 29, lines 591-595 and 599-601.

429 A. As I noted earlier, the Company conducted a load research study that collected customer
430 data for all residential NEM and non-NEM customers, as well as non-NEM data for all
431 other customer classes. The Company was only able to get NEM data for 36 residential
432 customers because it was only given permission to install production profile meters to
433 measure 15-minute interval data on the NEM customers' DG facilities (though 52 load
434 research profile meters were installed in total). The load research study spanned 12-
435 months and ended December 31, 2015, which was the test year for the cost of service
436 studies discussed above.

437

438 **D. Distribution Level Costs and Benefits of DG**

439 **Q. Does the Company believe that DG provides any distribution level benefits?**

440 A. No. The Company explains that not only does DG, and more specifically solar DG, not
441 reduce the system peak demand to a level that would help reduce the need for new
442 infrastructure, but it also may lead to increased infrastructure requirements.⁴⁶ In addition
443 to not reducing the peak demand, the Company states that NEM customers use the grid at
444 a higher level because they not only consume energy from the grid, but also export
445 energy to the grid which may in some cases overwhelm consumption. Further, the
446 Company claims it incurs additional costs due to applications for interconnection.

447

448 **Q. Did the Company provide any studies or data to back up its DG cost claims?**

⁴⁶ Direct Testimony of Douglas L. Marx, p. 2, lines 27-30.

449 A. Yes. The Company presented results from a rooftop solar study it conducted as part of the
450 2014 GRC (Docket No. 13-035-184). The purpose of the study was to evaluate rooftop
451 solar's impact on offsetting infrastructure upgrades made by the utility on the Company's
452 Northeast #16 circuit. Results of the study showed that DG was only able to offset seven
453 percent of the peak demand.⁴⁷ In addition, the Company conducted a similar study on its
454 Bingham #11 circuit and found a similar result (a 6.8 percent offset⁴⁸). The Company
455 used these results to reinforce its claim that increased DG penetration can lead to
456 increases in distribution system investments to control reverse power flows caused by the
457 DG systems.

458

459 **Q. What other system analysis did the Company perform?**

460 A. The Company analyzed solar peak output and system peak demand. According to the
461 Company, peak output of solar DG occurs during April or May and output decreases in
462 the summer months (June and July) when system peak demand typically occurs. Further,
463 the Company claims that peak demand occurs in the evening, when solar DG production
464 is at its lowest. Since peak solar DG production is occurring in April and May, the
465 Company explains that "the system may be sized up to 30 percent greater than normal. In
466 a few cases, the reverse power flow could approach 50 percent more as compared to the
467 customer's peak demand."⁴⁹ To emphasize a DG customer's grid usage, the Company

⁴⁷ *Id.*, pp. 2-3, lines 42-43.

⁴⁸ RMP response to DPU 8.1.

⁴⁹ Direct Testimony of Douglas L. Marx, p. 4, lines 75-77.

468 provided a power flow figure showing a 24-hour day in the summer for a typical 5 kW
469 DG customer.⁵⁰

470
471 Because of this increased grid usage by DG customers, the Company claims it will need
472 to make the following changes to its distribution system: “[a]dvanced metering to
473 monitor the system, updates in regulator, relay, and recloser controls to account for two-
474 way power flows [to] protect the system, [and] increased levels of voltage management
475 equipment and dead-line checking systems will be required.”⁵¹

476

477 **Q. What other costs does the Company discuss in relation to DG’s impact on the**
478 **distribution system?**

479 Additional costs of DG to the distribution system include application processing and
480 interconnection, which involves the Company’s customer call center, customer
481 generation, and engineering and operations departments. All applications are processed
482 under one of three levels of review. According to the Company, Level 1 applications are
483 about 80% of the total reviewed and apply to DG systems less than or equal to 25 kW
484 that operate with an inverter.⁵² Level 2 applications are those that do not qualify for Level
485 1 and are less than or equal to 2 MW. Level 3 applications are those that do not qualify
486 for Level 1 or Level 2 and are less than or equal to 20 MW. The Company claims that as
487 the level of review increases, the complexity of the review process increases, and so does

⁵⁰ *Id.*, p. 6, line 100.

⁵¹ *Id.*, pp. 4-5, lines 85-88.

⁵² *Id.*, p. 9, lines 169-170.

488 the cost, especially for the engineering department. Applications have been continuing to
489 increase each year and the Company is seeking cost increases to application fees to cover
490 the processing of applications.

491

492 **E. Rate Design**

493 **Q. Please explain the Company's proposed rate design.**

494 A. RMP is proposing to implement a three-part rate design for new residential NEM
495 customers based on its cost of service studies. The proposed rates include a fixed
496 monthly charge (customer charge), a time-based demand charge during peak hours, and
497 an energy charge. Additionally, the Company is seeking to place these NEM customers in
498 their own class because they have a different load shape and cost characteristics than
499 other residential customers. The new rates calculated from the proposed rate structure
500 would become effective June 1, 2017. Current residential NEM customers would not be
501 impacted by the proposed rate structure and would remain on their current rate schedule
502 because of the cost to “operationally and administratively”⁵³ transition these customers to
503 the proposed new rate schedule, including the need to change the current meters to meters
504 capable of capturing and billing the proposed on-peak demand charge. The Company also
505 proposes allowing the current residential NEM customers to opt into the new Schedule 5
506 rate tariff.

507

⁵³ Direct Testimony of Gary W. Hoogeveen, p. 11, line 233.

508 In addition, the Company seeks to eliminate the average retail rate compensation option
509 currently available for non-residential customers for their excess generation.

510

511 **III. ISSUES AND ANALYSIS**

512 **A. Need for Separate Residential NEM Class**

513

514 **1. Introduction**

515 **Q. What reason does the Company cite for putting residential NEM customers into a**
516 **separate rate class from residential non-NEM customers?**

517 A. The Company suggests placing NEM customers in a separate class because of differences
518 in load shape and cost characteristics. Specifically, the Company claims that NEM
519 customers have lower load factors than non-NEM customers and higher per unit customer
520 costs.⁵⁴

521 **Q. Have you evaluated the Company's claims regarding this issue?**

522 A. Yes, I analyzed the differences in load shapes and costs to serve NEM and non-NEM
523 customers using data from the Company's Load Research Study and the unit costs in the
524 NEM Breakout ACOS study.

525 **Q. Do you agree with the Company's conclusions about the need for a separate rate**
526 **class for residential NEM customers?**

⁵⁴ Direct Testimony of Joelle R. Steward, p. 18, lines 341-343.

527 A. As discussed in further detail in this section of my testimony, I agree there are differences
528 in the cost to serve NEM and non-NEM customers, but I have found the differences are
529 not as great as the Company claims.

530 **Q. Does your analysis consider the impact of excess generation exported to the grid?**

531 A. No, I only evaluated the costs to serve load provided by the grid for both NEM and non-
532 NEM customers.

533

534 **2. Load Research Study**

535 **Q. Why did you analyze the Company's load research study to evaluate whether NEM**
536 **customers should be in a separate rate class?**

537 A. The Company's load research study evaluates load shapes of NEM and non-NEM
538 residential customers and is used to estimate class load factors. A lower load factor for
539 NEM customers would indicate higher peak loads relative to average loads and vice-
540 versa. If demand-related costs are recovered through energy charges, as is typical for the
541 residential class, then a lower load factor indicates the need for a higher \$/kWh rate for
542 the class. The load research results also provide information as to whether NEM
543 customers are similar enough to each other that one rate for all NEM customers would be
544 reasonable.

545

546 **Q. How are residential NEM and non-NEM customers treated in the Load Research**
547 **Study?**

548 A. The Company divides all residential customers into four different strata based on
549 kWh/month usage. I provide a table below that summarizes the different strata and
550 provides a NEM vs non-NEM weight to the customers in each stratum. These weights
551 show that NEM residential customers appear to be more heavily concentrated in the
552 lower two usage strata. However, they may be more concentrated in the lower usage
553 strata due to consumption decreases associated with DG production.

554 **Table 3 – Residential Customer Strata Weighted for NEM and non-NEM.**

STRATA	NON-NEM WEIGHT	NEM WEIGHT
1: <500 kWh/month	0.29	0.35
2: 500-1,000 kWh/month	0.46	0.46
3: 1,000-2,000 kWh/month	0.22	0.15
4: 2,000+ kWh/month	0.02	0.03

555

556 **Q. Did you analyze the load shapes of the data collected for the load research study?**

557 A. Yes. I created two figures from the load research data the Company provided in
558 response⁵⁵ to UCE 7.8 (residential non-NEM customers) and in response⁵⁶ to EFCA 1.3
559 (residential NEM customers), which are provided below. They show the normalized
560 daily load shapes⁵⁷ for residential NEM and non-NEM customers. The residential non-
561 NEM customers, as shown in Figure 1, have very similar load shapes for strata 1, 2, and

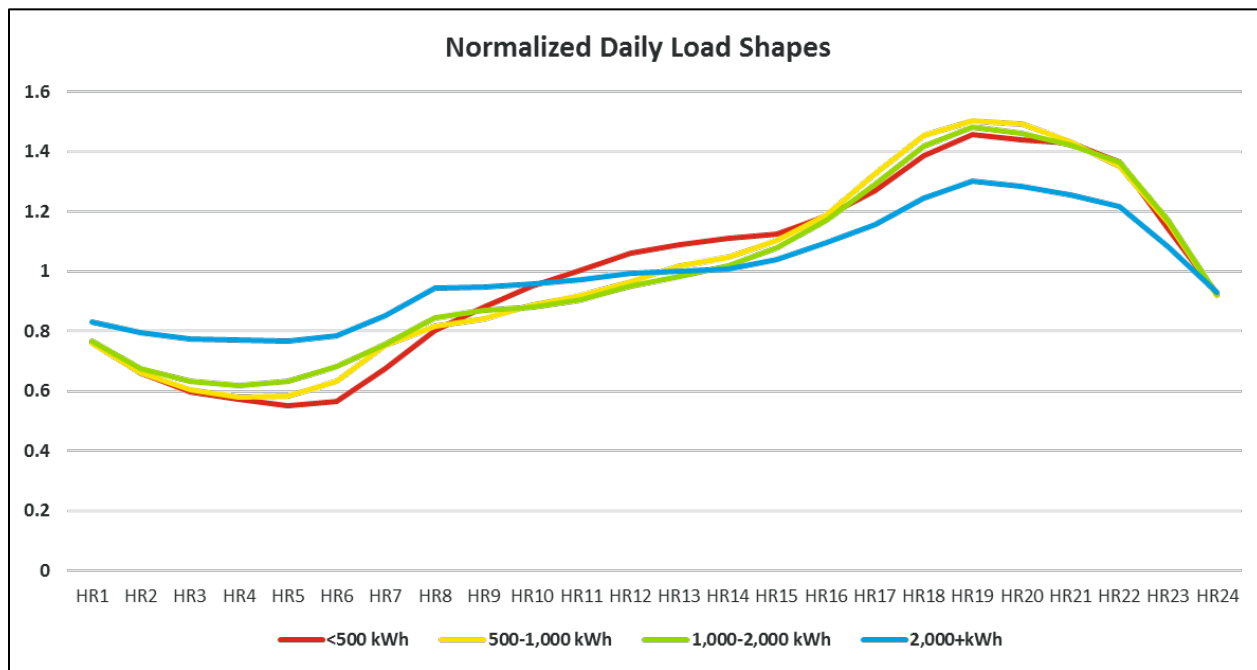

⁵⁵ See RMP response to UCE 7.8 Attachment [CONFIDENTIAL].

⁵⁶ See RMP response to EFCA 1.3 Attachment [CONFIDENTIAL].

⁵⁷ Normalized daily load shapes are constructed using the highest consumption value to set the base at 1.0, and then consumption was unitized relative to that 1.0 value to scale load shapes so they can be compared directly to one another regardless of consumption level.

562 3. Strata 4, which includes the higher-usage customers, has a flatter, but similar load
563 shape and thus a higher load factor.

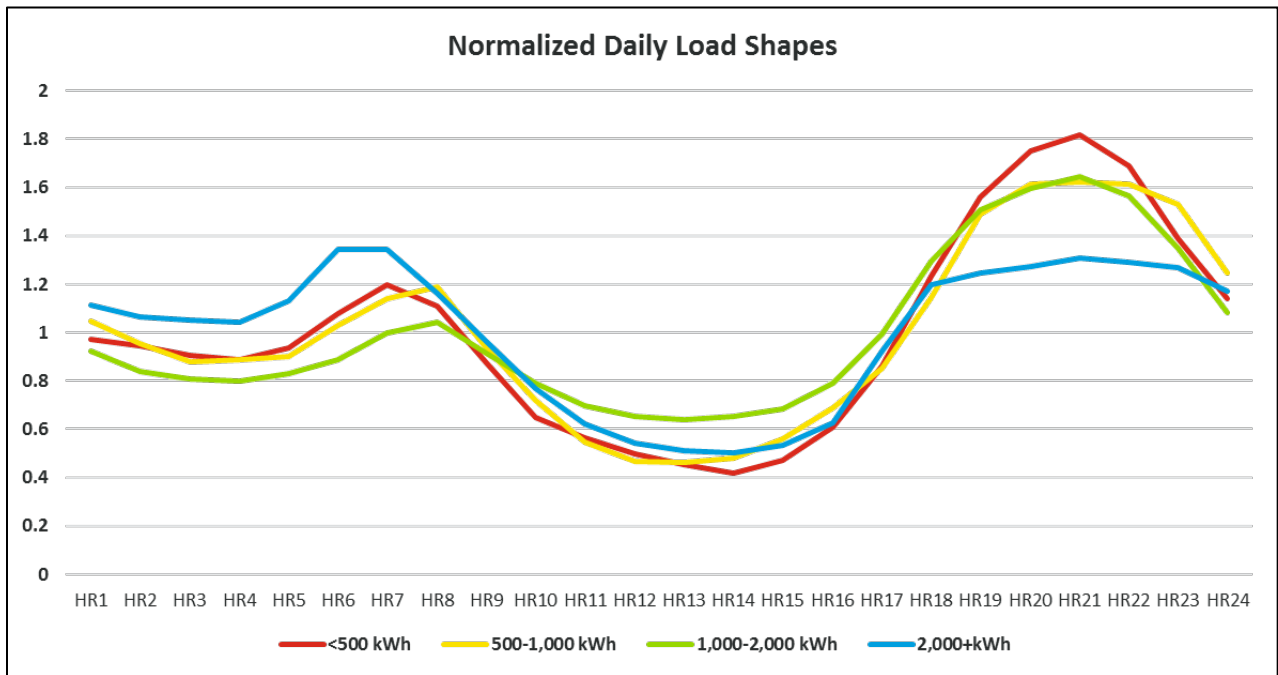

564 **Figure 1 – Residential Non-NEM Normalized Daily Load Shapes by Strata.**

565
566
567 The consumption pattern for the residential NEM customers depicted in Figure 2 is what
568 is known as a “duck curve.” This means that all four strata showed a morning peak
569 followed by low midday net consumption (after netting out DG production) that leads up
570 to a more prominent evening peak. As with non-NEM customers, the residential NEM
571 customers had very similar load shapes for strata 1, 2, and 3. Strata 4 had a similar shape
572 to the others, but was flatter.

573

Figure 2 – Residential NEM Normalized Daily Load Shapes by Strata.

574

575

576 **Q. What other data analysis did you conduct?**

577 A. I reviewed the individual residential customer load factors for NEM and non-NEM
578 customers based on the data provided by the Company in its responses to EFCA 1.3 and
579 UCE 7.8. Below I have provided a Box and Whisker plot that demonstrates that NEM
580 customers have a modestly lower average load factor and somewhat wider variation in
581 their load shape.⁵⁸

⁵⁸ The Box and Whisker plot shows an “x” and a line in each box that represents the mean of the data and the median of the data, respectively. The whiskers are the lines extending from the top and bottom of each box and indicates the relative distribution of the data. Notice some of the data points are outliers that fall outside of this distribution.

582

Figure 3 – Residential Individual Customer Load Factors.

583

584

585 In addition to this analysis, I compared residential class load factors for NEM and non-
586 NEM customers based on data from the NEM Breakout ACOS study and from load
587 research data⁵⁹ provided by the Company. The table below shows the results of this
588 comparison, which also supports the conclusion that although NEM customers as a
589 separate class have a slightly lower load factor than non-NEM customers, they are not
590 drastically different.

⁵⁹ From RMP responses to EFCA 1.3 and UCE 7.8

591

Table 4 – Residential Class Load Factors.

		Non-NEM	NEM
15-minute Interval	12 NCP (kW)	56,098,384	387,862
	Average Load (kW)	744,664	4,466
15-minute Interval	12 NCP Load Factor	16%	14%
Hourly Interval	1 NCP (kW/customer)	2.94741	3.386
	Average Load (kW/customer)	0.973359	1.053
Hourly Interval	1 NCP Load Factor	33%	31%

592

593 **Q. What do you conclude from your analysis of the Load Research results?**

594 A. NEM customers do have a different load shape than non-NEM customers. More
595 specifically, NEM customers exhibit the “duck curve” shape that has lower midday net
596 consumption followed by a rapid rise in demand at sunset. However, this difference in
597 load shape does not translate into large differences in annual load factors. There is also
598 more variation in the load factors of the NEM customers, but not drastically so. Below I
599 analyze unit costs to see if the load factor differences translate into the need for different
600 rates.

601

602 **3. Total Unit Costs**

603 **Q. What is the purpose of your unit cost analysis?**

604 A. Total unit costs show the allocated COS for each rate class divided by the number of kW,
605 kWh, and customers within the class. A considerably different unit cost would indicate a
606 higher or lower cost to serve each unit of demand or to serve each customer and could
607 indicate the need for a separate rate class.

608

609 **Q. What are the results of your unit cost analysis?**

610 A. Based on data in the ACOS NEM Breakout study, I determined that the NEM and non-
611 NEM residential customers have similar unit costs, which are shown in the table below.
612 The similarity in energy unit costs are particularly striking. These numbers indicate that if
613 NEM and non-NEM residential customers were in different classes and the Company
614 used a fixed dollar per kWh charge to collect all revenue from residential customers, the
615 rate for each class would only vary by 0.2 cents/kWh. Such a difference, on its own,
616 would not typically warrant the added costs and complexity of creating another rate class.

617

Table 5 – Residential Class Unit Costs.

	Non-NEM	NEM	Difference
Total COS/NCP kW	\$13.36	\$11.82	-11%
Total COS/kWh	\$0.115	\$0.117	2%
Total COS/Customer	\$999.45	\$1,044.45	5%

618

619 **4. Customer Unit Costs**

620 **Q. Please explain the difference between total unit costs and customer unit costs.**

621 A. Customer unit costs relate only to costs classified as customer-related in a COS study.
622 Here, I define customer related costs as the costs of the meters, services, and retail

623 subfunctions in the ACOS model. These costs vary most directly with the number of
624 customers. For residential customers, these costs are often collected through fixed
625 monthly customer charges and not energy charges.

626

627 **Q. What are the customer unit costs for residential NEM and non-NEM customers**
628 **based on the Company's NEM Breakout ACOS study?**

629 A. The table below shows the customer unit cost for each class. I divided the \$/customer
630 annual number by twelve to estimate what the rate would be if the customer costs were
631 collected as a fixed monthly charge. As the table shows, based on the Company's results,
632 NEM customers have close to twice the customer unit costs as non-NEM customers.

633 **Table 6 – Customer unit costs for residential NEM and non-NEM classes showing higher**
634 **customer unit costs for NEM customers. Per numbers from RMP's NEM Breakout ACOS**
635 **study.**

	RES NON-NEM	RES NEM
Customer Cost (\$/customer/month)	\$6.64	\$12.58

636

637 **Q What is driving the differences between these customer unit costs?**

638 A. The table below shows the difference in unit costs for each category of customer-related
639 costs. Notice that unit costs for NEM customers are higher for metering, services, and
640 retail subfunctions.

641 **Table 7 – Customer unit costs by subfunction in \$/customer/month. Per numbers from**
642 **RMP’s NEM Breakout ACOS study.**

643

	RES NON-NEM	RES NEM
Services	\$2.69	\$3.30
Meters	\$0.65	\$1.16
Retail	\$3.30	\$8.12
TOTAL	\$6.64	\$12.58

644

645 **Q. How did residential metering costs differ between NEM and non-NEM customers?**

646 A. NEM customers require a bidirectional meter, meaning a meter capable of measuring
647 both energy flows from and to the grid. These meters are costlier than standard residential
648 meters as shown in the table below.

649 **Table 8 – Residential metering costs for NEM and non-NEM customers. Based on data**
650 **from the Company’s NEM Breakout ACOS study.**

<u>Load Class</u>	<u>Standard</u>	<u>Installed Cost</u>	<u>Percent Use</u>	<u>Total Installed Cost / Service</u>
<u>Residential (Non-NEM)</u>				
Small Load	DM221F	\$104	92.1%	\$95.83
Large Load	DM221G	\$139	7.9%	<u>\$10.93</u>
				\$106.75
<u>Residential (NEM)</u>				
Bi-Directional,				

kW = 0, 1 Phase (sec)	DM221B	\$162	100.00%	\$162.00
-----------------------	--------	-------	---------	----------

651

652 **Q. How did residential service drop costs differ between NEM and non-NEM**
653 **customers?**

654 A. The assumed cost of each type of service drop was the same for residential NEM and
655 non-NEM customers. However, the table⁶⁰ below shows that a higher proportion of
656 residential NEM customers were underground service customers. This results in the NEM
657 customer service drop cost being higher per customer because of the higher cost of
658 underground service.

659 **Table 9 – Percentages of NEM and non-NEM customers by overhead and underground**
660 **service type.**

	Residential Non-NEM	Residential NEM
OH – small load	31.18%	22.04%
OH – all electric	2.66%	2.34%
UG – small load	60.96%	71.01%
UG – all electric	5.20%	4.61%

661

662 **Q. Please explain the retail function costs for NEM customers.**

663 A. The higher unit cost of NEM customers is driven largely by the direct assignment of
664 administration and customer service costs to these customers. The table below provides
665 the total dollars the Company assigned directly to the residential NEM class. The total
666 incremental cost is net of Application fee revenue. The revenue for residential customers

⁶⁰ In the table, overhead = OH and underground = UG.

667 in the 2015 test year was only \$138, but RMP proposes to increase this fee as is discussed
668 in a later section of my testimony. With an increased application fee, it would not be
669 necessary to recover these costs through the customer charge.

670 **Table 10 – Retail function costs for NEM customers.**

	Residential NEM	Schedule 23 NEM
Estimated Incremental Cost of Administration	\$198,752	\$16,110
Application Fee Revenue	(\$138)	(\$7,404)
Estimated Incremental Cost of Customer Service Cost	\$75,247	\$4,415
Total Incremental Cost of Administration & Customer Service	\$273,861	\$13,120
Total Cost/Customer/Month	\$5.20	\$3.35

671

672 **Q. Please explain the Company’s Residential Customer Charge proposal.**

673 A. The Company proposes to increase the customer charge to more than double the current
674 amount. The new proposed customer charge includes all service, meter, and retail
675 function costs plus a transformer cost.⁶¹ The charge is estimated net of expected revenue
676 from the Company’s proposed application fee. The table below highlights the cost
677 differences in the customer charge and minimum bill by phase type under the current and
678 proposed customer charge regime.

679 **Table 11– Comparison of Current and Proposed customer charge.**

		Current	Proposed
Customer Charge	1-Phase	\$6.00	\$15.00

⁶¹ See Direct Testimony of Joelle R. Stewart, Table 3, p.15 and pp. 22, 25-27; Approved Tariff.

Customer Charge	3-Phase	\$12.00	\$30.00
Minimum Bill	1-Phase	\$8.00	\$15.00
Minimum Bill	3-Phase	\$16.00	\$30.00

680

681 **Q. Please explain the issues with costs the Company is including in its proposed**
682 **customer charge.**

683 A. The Company is proposing to include a customer charge for new NEM customers that
684 “is designed to recover costs related to customer services and certain components of the
685 distribution system, specifically service lines, meters, and line transformers”.⁶² While a
686 customer charge is typically designed to recover customer-related costs, it does not
687 typically include transformer costs. In fact, the Commission has been consistent since its
688 1982 Order⁶³ detailing costs a customer charge should recover, and they do not include
689 transformer costs.

690

691 **Q. How much would residential customer charges increase if designed to recover**
692 **transformer costs?**

693 A. Featured below is a table outlining the transformer costs by NEM and non-NEM
694 customer class per the Company’s NEM Breakout ACOS model. Based on these
695 numbers, recovering transformer costs through the customer charge would increase that
696 charge significantly, but even more so for NEM customers than non-NEM customers.

⁶² Direct Testimony of Joelle R. Steward, p. 22, lines 403-405.

⁶³ Docket 82-057-15, Aug 12 1983, Questar Gas Company case. There was a later docket with PacifiCorp, 84-035-01 Jul 1, 1985.

697 **Table 12 – Transformer unit costs per customer. Based on data from the Company’s NEM**
698 **Breakout ACOS Study.**

	Res Non-NEM	Res NEM
Per Customer per Month	4.21	7.53

699

700 **Q. Why does the Company recommend that transformer costs be recovered through**
701 **the customer charge for NEM residential customers?**

702 A. Ms. Stewart argues that “a large proportion of the costs of these transformers do not vary
703 with capacity and are fixed infrastructure costs necessary to serve customers”⁶⁴ The
704 Company has argued that the additional distribution system costs associated with NEM
705 systems—such as transformer upgrades to accommodate bidirectional flows—justifies
706 different treatments of transformer costs for rate design.

707

708 **Q. Do you agree that transformer costs should be included in the customer charge for**
709 **any customer class because a large portion of the costs are fixed costs?**

710 A. No. In my previous testimony⁶⁵, I did not recommend that transformer costs be included
711 in the customer charge for residential customers, and I stand by that recommendation.
712 Although these costs may be considered fixed, this does not by itself justify their
713 inclusion in the customer charge. The customer charge should generally consist of costs
714 that truly vary with the number of customers, which would not include the costs of all
715 fixed utility plant.

716

⁶⁴ Direct Testimony, pp. 26-27.

⁶⁵ Docket 13-035-184, Faryniarz Direct Cost of Service Testimony for DPU - 05-22-2014 - Exhibit 11.0 DIR-COS.
Docket 13-035-184, Faryniarz Rebuttal Cost of Service Testimony for DPU - 06-26-2014 - Exhibit 11.9 REB-COS.

717 **Q. Do you agree that increased distribution transformer costs for NEM customers**
718 **justifies the recovery of transformer costs in the customer charge?**

719 A. No. Just because the cost is higher for a given class does not mean it should be recovered
720 in the customer charge. Customer charges should recover customer-related costs, and
721 transformer costs do not vary directly with the number of customers. If there is a need for
722 transformer upgrades to interconnect a DG system, then the cost of the upgrade is best
723 recovered from the connecting customer through an interconnection charge. I discuss
724 these charges in more detail later in my testimony.

725

726 **Q. Did you find any other issues with the discussion of transformer cost allocation in**
727 **Ms. Stewart's testimony?**

728 A. Yes. There are inconsistencies in terms of how transformer costs are classified by the
729 Company. In Table 5 (p.20) of Ms. Stewart's testimony, which purports to show the
730 significance of demand-related costs in a utility's COS, transformers are featured as
731 demand-related costs. Then later in her testimony when attempting to justify the inclusion
732 of transformer costs in the customer charge, she argues the costs are mostly customer-
733 related. This seems to indicate some cherry-picking in how the Company presents these
734 costs in its analysis.

735

736 **Q. The numbers in Table 12 above also indicate that transformer costs for NEM**
737 **customers are significantly higher per customer than non-NEM customers. Do you**
738 **agree with this finding?**

739 A. No. Transformer costs are allocated using a 1NCP allocator. The NCP for NEM
740 residential customers increases uniformly throughout the test year as previously non-
741 NEM customers switch to NEM service. Therefore, the NCP for the NEM residential
742 class is in December, at the end of the year. The NCP for the non-NEM residential class
743 is in July. This double counts some customers that switch to NEM service between July
744 and December and, therefore, over-allocates costs to residential customers. If we use the
745 July NCP for both residential NEM and non-NEM customers, the transformer unit costs
746 for NEM customers decreases to \$5.32/customer.

747

748 **Q. What do you recommend regarding transformer cost allocation?**

749 A. I recommend the Company ensure that the transformer allocator does not double count
750 customers in its NCP calculation. This should reduce costs allocated to the NEM
751 residential class for the NEM breakout ACOS study.

752

753 **5. Conclusions**

754 **Q. Should NEM customers be segregated into their own class from non-NEM**
755 **customers?**

756 A. Based on my analysis and findings described above, it is not necessary, for now and at
757 the current level of penetration, to separate NEM customers into their own class. As I
758 explained earlier, the NEM load profiles are somewhat different than the non-NEM load
759 profiles, especially during the middle of the day, but on average fall within a reasonably
760 similar range (see Figure 3 presented previously).

761

762 In addition, I do not conclude that a separate class for NEM customers is warranted in
763 order to increase customer charges for these customers. NEM customers do require
764 modestly higher metering costs, but that difference alone does not justify a higher
765 customer charge. Changes in service drop costs are driven more by other characteristics
766 of the customers, such as placement on the underground or overhead system. Additional
767 administrative costs for the NEM program—if assigned only to NEM customers—or
768 increased transformer costs necessary to accommodate bidirectional flows, are best
769 recovered through an alternative charge such as an application fee or interconnection fee
770 as discussed later in this testimony.

771

772 Despite this, I do not object to the separation of NEM customers into a separate class if
773 deemed appropriate for other policy reasons, or to address compensation rates for excess
774 generation exported to the grid, which I turn to next.

775

776 **B. Importance of Net Energy Metering Excess Generation Credits for**
777 **Residential Customers**

778 **Q. As described in the previous section of your testimony, you did not find a significant**
779 **difference in the costs to serve NEM versus non-NEM residential customer load. If**
780 **so, what is driving the difference in revenue parity to COS shown in Table 2 above?**

781 **A.** As I previously indicated, my analysis of the need for a separate class for NEM
782 residential customers did not account for credits for excess generation exported to the
783 grid. As I explain in more detail below, compensation for these exports at retail rates is

784 the primary driver of the low revenue parity ratio shown in Table 2 for NEM residential
785 customers.

786

787 **Q. How does the Company credit distributed generation (DG) exports in its NEM**
788 **Breakout ACOS model?**

789 A. Excess NEM generation is credited at average net power costs (NPC) grossed up for
790 transmission and distribution losses. These are shown in the table below.

791 **Table 13 – Credit rates for excess NEM generation credits in Company NEM Breakout**
792 **ACOS study.**

	NPC + Losses
Summer (cents/kWh)	2.8304
Winter (cents/kWh)	1.9539

793

794 **Q. Do residential customers currently receive compensation for grid exports based on**
795 **NPC rates?**

796 A. No. NEM customers are in effect reimbursed at retail energy rates because they are billed
797 for the net of total consumption minus total exports. Current retail rates for residential
798 customers are summarized in the table below. They are much higher than average NPC.

799 **Table 14 – Current residential energy charges for RMP customers. Tiers apply based on**
800 **kWh consumed each month with higher tiers applicable to higher levels of consumption.**

	Tier 1	Tier 2	Tier 3
Summer (cents/kWh)	8.8498	11.5429	14.4508

Winter (cents/kWh)	8.8498	10.7072	N/A
---------------------------	--------	---------	-----

801

802 **Q. If excess NEM generation is credited at retail rates instead of average NPC, how**
803 **does that change the COS results?**

804 A. To answer this, I increased excess NEM credits to the highest tier retail rates in the
805 Company’s NEM Breakout ACOS model. The result is summarized in the table below.
806 Parity to COS for residential NEM customers increases drastically: from 60.6% to over
807 90%, bringing it much closer to the parity ratio for non-NEM customers.

808 **Table 15 – Parity to COS for NEM and non-NEM customers assuming different rates NEM**
809 **export credit rates.**

	Credit at Net Power Cost	Credit at Retail Rate*
Non-NEM	96.1%	96.0%
NEM	60.6%	90.5%

810 * Assumed Highest Tier Rate: 10.7072 cents/kWh (Winter) 14.4508 cents/kWh (Summer)

811

812 **Q. Please elaborate on the significance of the excess NEM credit rate to the NEM**
813 **breakout ACOS results.**

814 A. The results in the table above demonstrate the importance of valuing excess NEM
815 generation consistently in an ACOS study. The results indicate that if one accepts the
816 Company’s COS methodology and then compensates excess NEM generation at a rate
817 based on NPC plus losses, and if residential NEM customers were in a separate class but
818 paying the Company the same rate as other residential customers for the load served from

819 the grid, revenues from NEM customers would cover on the order of 90% of cost of
820 service, not the 61% covered today when excess generation is compensated at full retail
821 rates. The remaining difference in parity to COS between non-NEM and NEM customers,
822 that is the difference between the 96% and the 90%, is due to other differences in the
823 COS for these customers, such as from different load shapes or unit costs discussed in the
824 previous section. Those differences are, notably, much smaller.

825

826 **Q. Is the value of excess NEM generation also a key driver to the CFCOS results?**

827 A. Yes. The CFCOS study attempts to estimate costs to the utility if the customer generation
828 from NEM facilities did not exist. The added costs are largely from increased NPC at the
829 rates shown in the table below. These rates are similar to the NPC rates used in the NEM
830 Breakout ACOS, but of course much lower than residential retail energy rates. Therefore,
831 under the Company's assumptions, if one adds the NEM generation back to the CFCOS,
832 costs decrease less than utility revenues, indicating the NEM program results in a net cost
833 to other customers and the utility.

834 **Table 16 – Average cost of additional NPC assumed to be required to generate power to**
835 **replace generation from NEM customers in CFCOS study.⁶⁶**

	Added NPC in CFCOS
Summer (cents/kWh)	2.9334
Winter (cents/kWh)	2.1692

836

⁶⁶ See Exhibit RMP_(MGW-1) and see RMP response to DPU 6.12-1, Exhibit RMP_(MGW-1) CORRECTED.

837 **Q. Is there a strong logical basis for valuing excess NEM generation at retail rates?**

838 A. No. Retail rates are based on the total costs to serve customers from a grid-based system,
839 which has nothing to do with the costs of supplying power from DG systems. Thus, they
840 are not equivalent to the benefits of DG systems. Moreover, the ability to export and
841 receive compensation at retail rates allows customers to effectively zero out their energy
842 bills as long as total generation is equal to total load consumed, regardless of the time the
843 energy is consumed or generated.

844
845 Consider an extreme case, where a utility served only such customers. The utility would
846 receive no revenue even though it would incur significant costs to store the excess energy
847 and supply it back to customers. Thus, traditional NEM excess energy compensation, at
848 full retail rates, is not sustainable in the long-run with very high rates of DG penetration.

849

850 **Q. What possible options exist for valuing exports?**

851 A. Besides the de facto retail rate reimbursement paradigm, exports could be valued
852 numerous ways. These include using the avoided costs of fuel and purchased power
853 (short-term), generation capacity (long-term), or the avoided costs of utility-scale
854 renewable resources. Additional costs and benefits to the transmission and distribution
855 systems could also be considered, as well as environmental benefits and local economic
856 benefits. I turn to these factors next.

857

858 **C. NEM Costs and Benefits**

859 **Q. The Company's response to OCS 6.7 discusses several costs and benefits that were**
860 **either included or excluded from the cost of service studies. These costs and benefits**
861 **include the following: NEM added Program Administration Costs, NEM added**
862 **Integration costs, NEM added Distribution Costs, NEM added Lost Revenues,**
863 **Avoided Energy Costs, Avoided Capacity Costs, Avoided Transmission Costs,**
864 **Avoided Distribution Costs, Avoided T&D Line Losses, and Avoided Environmental**
865 **Compliance. Do you agree with the Company's inclusion/exclusion of each of these**
866 **costs?**

867 A. In general, the foregoing categories of costs and benefits of NEM appear reasonable for
868 the Company to consider including in its cost of service studies. For each of the NEM
869 cost categories, the Company included these costs in its cost of service studies. Regarding
870 program administration costs, the Company explained that it has one department across
871 the six states it serves that is responsible for administering the NEM programs. Costs are
872 assigned to each state proportionally based on overall department expenses allocated to
873 each state's NEM program. Application fee revenues from large non-residential
874 interconnections collected in 2015 reduced the total expense. After review of the total
875 expenses allocated to each state, calculated in Exhibit RMP_(RMM-7), the allocation of
876 the Company's NEM department's expenses to Utah appear to be reasonable.

877

878 The Company included NEM integration costs in its net power costs because these costs
879 are incurred when integrating new private distributed generation into the system, which
880 includes added reserves needed to handle the private DG's intermittency (i.e. inability to

881 continuously supply a customer's full power needs). Integration costs can increase or
882 decrease the net power costs depending on if private DG is added or taken off the system.
883 The Company explained that it used solar integration costs in its net power cost analysis
884 of \$2.83/MWh.⁶⁷

885
886 The Company states that the NEM program adds incremental metering and engineering
887 costs to the distribution system.⁶⁸ The engineering expenses are solely related to the time
888 engineers spend reviewing NEM applications, which can vary in complexity.⁶⁹
889 Incremental metering costs are related to replacing and reprogramming⁷⁰ customers'
890 current meters with bi-directional meters that can measure the flow of energy to and from
891 the installed DG facilities. When estimating the percentage of meters that can be
892 reprogrammed versus replaced, the Company bases the percentages of either option on
893 the current proportion of meters that have been reprogrammed or replaced.⁷¹ Both costs
894 seem reasonable, as detailed in exhibits⁷² provided by Company witness Mr. Meredith.
895

896 The Company considered lost revenues associated with the NEM program as a cost due
897 to bill credits. Bill credits are calculated based on the difference between the Company
898 providing customers full energy requirements and the actual energy customers are billed

⁶⁷ This is consistent with the Commission's Order in the QF Docket. Docket No. 12-035-100, Order on Phase II Issues, at 34 (Utah P.S.C. August 16, 2013). Direct Testimony of Michael G. Wilding, p. 8, lines 138-140.

⁶⁸ RMP response to OCS 6.7(c). Direct Testimony of Robert M. Meredith, p. 17, lines 328-347.

⁶⁹ See Exhibit RMP_(RMM-8) for a breakout of the engineering expenses by customer class.

⁷⁰ Residential customers need to have their current meters replaced, while some non-residential customers have meters capable of measuring the bi-directional energy flows, but need to have the meters reprogrammed to do so.

⁷¹ See Exhibit RMP_(RMM-9), Page 1&2, Notes.

⁷² Exhibits RMP_(RMM-8) and RMP_(RMM-9).

899 for each month.⁷³ A revenue difference is calculated based on multiplying the
900 corresponding energy charges by the difference between providing full energy
901 requirements and billed energy. In calculating the bill credits related to the NEM
902 program, the Company relied on the results of the CFCOS (without DG) versus the
903 ACOS (with DG).⁷⁴

904
905 All the costs the Company considered for the NEM program appear reasonable as costs to
906 consider. However, as discussed earlier, reliance on the CFCOS results may lead to
907 inaccurate NEM program costs. Since the CFCOS is based on going back in time and
908 assuming the Company needed to provide full requirements service to all customers, the
909 Company is assuming the private generation plus the actual billed energy for each
910 customer would be equal to each customer's total energy needs.

911
912 **Q. Do you agree with the Company's inclusion/exclusion of each of the benefits listed**
913 **above?**

914 A. First, the list of benefits that the Company was asked if it considered in its cost of service
915 studies is not a complete list of all possible benefits that could be reviewed, i.e. several
916 types of environmental or economic benefits could also be analyzed. Second, many of the
917 avoided costs were not explicitly included by the Company in its cost of service studies.
918 For example, the Company explains that avoided transmission costs, avoided distribution
919 costs, and avoided environmental compliance are not explicitly included, but instead are

⁷³ The Company created seasonal energy blocks and on-peak and off-peak periods when it could do so.

⁷⁴ See Exhibit RMP_(RMM-5).

920 considered a “benefit for reduced allocations of existing costs”⁷⁵. Further, the Company
921 explained that during the cost of service study period, which is a one-year test period
922 starting January 1, 2015, the transmission costs, distribution costs, and environmental
923 compliance costs “were not reduced as a result of the NEM program”⁷⁶. Since the
924 Company is using a one-year historic test-period as discussed from the Phase I
925 Commission Order, it is likely that any long-term transmission, distribution, and
926 environmental compliance avoided cost benefits may not be able to be properly captured.
927
928 Avoided distribution costs, which potentially can reduce the need for the Company to
929 replace, upgrade, or expand its distribution system capacity due to system or localized
930 peak reductions, would need to be analyzed over a longer period of time and should also
931 be analyzed for providing location-specific benefits when possible. The Company did
932 complete two location-specific analyses (Northeast #16 and Bingham #11 circuit studies),
933 which it stated resulted in rooftop solar minimally reducing the peak circuit loading in
934 two different locations.⁷⁷ In addition, the Company claims that it “will need to increase
935 the size of the local distribution system to handle the reverse power flow delivered to the
936 grid by the customers”.⁷⁸ While these two studies do indicate minimal localized circuit
937 peak load reduction on the selected circuits, it is possible that rooftop solar may have
938 greater impacts on other circuits or help further reduce the system peak, since there has

⁷⁵ RMP response to OCS 6.7(g), (h), and (j).

⁷⁶ *Id.*

⁷⁷ Direct Testimony of Douglas L. Marx, pp. 2-3, lines 38-54.

⁷⁸ *Id.*, p. 3, lines 62-63.

939 been an exponential amount of solar added to the Company's system over the last few
940 years.

941
942 However, it will be important to address how, if at all, such potential reductions might be
943 reflected in base rates or compensation levels for NEM customers because such benefits
944 do not fit well within traditional test year studies.

945
946 Furthermore, the reverse power flow issue that Company witness Marx describes is not
947 addressed in Exhibit RMP_(DLM-1), the July 26, 2015 Distribution Rooftop Solar Study,
948 nor is it presented by the Company in any quantifiable way.

949
950 **Q. How did the Company include avoided energy and capacity costs in its cost of**
951 **service studies?**

952 A. The Company explained that avoided energy costs were "included as a benefit for
953 reduced NPC as well as for reduced energy based allocations" and avoided capacity costs
954 were "included as a benefit for reduced demand based cost allocations".⁷⁹ In calculating
955 the benefits of the NEM program to the NPC, the Company went from a system with
956 private distributed generation to one with no private DG, meaning the Company would
957 have to provide full requirements energy to all customers. This included changes to the
958 amount of generation and market transactions to make up for the loss of private DG.
959 RMP explained that net benefits to the system from private DG were calculated by

⁷⁹ RMP response to OCS 6.7(e) and (f).

960 multiplying the actual costs of generation and market transactions by the incremental
961 changes to each needed to make up for the loss of private generation.⁸⁰ Then, since DG
962 interconnection costs are treated as an avoided cost in the NPC calculation, the
963 \$2.83/MWh for solar DG interconnection costs is treated as a reduction to the NPC. So,
964 the Company reduced the total unit value of solar in \$/MWh by the \$2.83/MWh
965 integration cost before multiplying the total unit value of solar by the MWh generation
966 from private generation to get the total net power cost benefit of the state's NEM
967 program.⁸¹

968
969 The Company created a standardized production profile using data from 36 production
970 profile meters that were installed on private DG systems during the load research study.
971 This production profile enabled the Company to estimate private DG production, which
972 the Company would need to supply customers in the CFCOS study because they no
973 longer have such private generation to rely on for part of their energy needs. So, the loss
974 of private DG production would result in an increase in demand in the state, and could
975 potentially increase state load interjurisdictional allocations (whether they be interstate or
976 intrastate). Thus, the CFCOS had its allocation factors modified to reflect what they
977 would have been without private DG production.

978

979 **Q. Did the Company include a benefit for avoided line losses, and if so, how?**

⁸⁰ Direct Testimony of Michael G. Wilding, p. 2, lines 33-35.

⁸¹ This was done monthly.

980 A. Yes. The Company had to figure out the line losses applied to private generation to
981 calculate the avoided line loss benefit to the system. RMP explained that it determined
982 the nameplate installed capacity each month for customers served at both the primary and
983 secondary voltage levels. Then the Company used loss factors from a 2015 COS study
984 for the nameplate capacity quantities to expand the private generation by class and
985 ultimately bring it to the input level.⁸² While the Company's method to calculate avoided
986 line losses is a reasonable proxy, it could potentially under- or over-estimate actual line
987 losses avoided, depending on distance to certain generation facilities, distribution line
988 length, and distribution equipment for each customer.

989

990 **Q. Are there other avoided costs or benefits to the distribution system the Company**
991 **should have considered in the cost of service studies?**

992 A. There are other potential avoided costs or benefits to the distribution system the
993 Company could consider in its cost of service studies, insofar as they are quantifiable and
994 not double-counted. These possible benefits of DG to the distribution system include
995 environmental, societal, and market benefits.

996

997 Notably, in its July 1, 2016 Order, the Commission explained that benefits should be
998 within the Company's control. However, environmental, societal, and market benefits are
999 typically not considered within the Company's control. In addition, the Company actively

⁸² Direct Testimony of Robert M. Meredith, p. 14, lines 267-274.

1000 does environmental control, and any environmental benefits in addition to that could be
1001 considered double-counting in this category of benefits.

1002
1003 In other jurisdictions, Commissions have considered these benefits of DG to the
1004 distribution system, but have typically done so through opening separate dockets or
1005 proceedings. The reason for separating out costs and benefits in a different docket is to
1006 allow for proper, focused analysis and stakeholder vetting of each.

1007

1008 **Q. Should the Utah Public Service Commission consider expanding the current docket**
1009 **or opening a separate proceeding to ensure a robust analysis of DG benefits and**
1010 **costs over a longer planning horizon?**

1011 A. Yes. I would recommend that the Commission consider opening a separate docket to
1012 properly vet possible DG costs and benefits to RMP's distribution system, potentially to
1013 include parties to the current docket and all stakeholders with an interest in DG. Such a
1014 process would take considerable time but need not forestall transitional rate changes in
1015 the interim that might lead to better-designed rates than currently exist.

1016

1017 **D. Residential Demand Charge for new NEM Customers**

1018 **Q. Please explain the issues with implementing a demand charge.**

1019 A. Using demand charges to recover transmission and distribution ("T&D") costs can be
1020 justified under cost causation principles, as T&D systems are designed to meet aggregate
1021 peak demand and are mostly fixed cost in nature. Coincident or TOU demand charges,

1022 which have been proposed by the Company, can send a better price signal than demand
1023 charges based on maximum billed demand in each billing cycle, and thus will better
1024 reflect the cost causation principles of ratemaking. This may be largely academic,
1025 however, since metering currently in place, outside of the load research study⁸³, does not
1026 allow for measurement of coincident or TOU demands.

1027
1028 It would also be difficult to implement demand charges for residential customers at this
1029 point for several reasons, including higher costs for new metering that would be
1030 necessary for implementing such charges, as well as a lack of and cost for customer
1031 outreach and education, and anticipated issues with general customer acceptance.⁸⁴
1032 Because demand charges, with or without ratchets⁸⁵, can affect customer bills
1033 significantly, there is also the potential for significant rate shock and dislocation, which
1034 would violate another key ratemaking principle of rate stability.⁸⁶

1035

1036 **Q. What would you recommend regarding demand charges?**

1037 A. Demand charges have the potential to better reflect cost causation on the distribution
1038 system, especially if they are based on coincident peak or are time-differentiated.

1039 However, based on issues regarding the installation and cost of required metering capable

⁸³ *Id.*, p. 10, lines 183-186.

⁸⁴ See additional discussion of these topics in *Distributed Energy Resources Rate Design and Compensation: A Manual* Prepared by the NARUC Staff Subcommittee on Rate Design (November 2016), pp. 98-108.

⁸⁵ An example of a ratchet is when the demand charge is based on historical peak demand. If the peak demand from the previous summer was 100 kW and a company had a 50% ratchet, the minimum billing demand would be 50 kW (100 kW times 50%) for a set number of months. Under this structure, it would not matter if actual demands were lower.

⁸⁶ Bonbright, James C., *Principles of Public Utility Rates*, pp. 383-384 (1988) (rate structure characteristics).

1040 of recording demands over all hours of the billing cycle, customer acceptance and
1041 understanding, ability to monitor and control electricity bills, and the potential for rate
1042 shock and dislocation, I recommend demand charges be implemented gradually. Further
1043 data collection, including on DG and non-DG customer load shapes and the impacts on
1044 residential customers where such charges have been implemented in other jurisdictions, is
1045 warranted to better understand the effects of demand charges on gross and net
1046 consumption and how these charges would impact DG resource development on a
1047 forward-looking basis. I recommend the Commission concurrently consider alternative
1048 rate designs or other ratemaking tools to address problems with current rates.

1049

1050 **Q. What alternatives to demand charges could be considered?**

1051 A. *Demand* charges that are time-based or based on coincident peak demand can be effective
1052 at signaling the times of highest long-term cost on the aggregate utility system, including
1053 the distribution system. On the other hand, a TOU or other time-differentiated *energy*
1054 rate with higher charges during hours of the day when the residential class typically peaks
1055 (i.e., early evening), would also reflect cost causation and send an appropriate price
1056 signal.

1057

1058 TOU pricing is generally viewed more favorably among a broad variety of non-utility
1059 stakeholders, and may be preferable at this point to the proposed demand charges or other
1060 fixed charges. Properly-designed TOU or other time-differentiated energy rates can
1061 reflect changes in hourly energy prices throughout the daytime and seasons and therefore

1062 serve as an appropriate determinant for recovery of many fixed costs associated with
1063 T&D service as well as better reflecting market prices for energy. Under TOU or other
1064 time-differentiated energy rates, regardless of when a customer sets a peak demand, the
1065 customer still has an incentive to adjust energy consumption, add DG, or both, in
1066 response so that it can benefit from lower bills if the customer can shift usage to lower
1067 TOU rate periods going forward. In addition, the use of super or “critical” peak TOU
1068 periods during times of peak demand on the overall system and/or the utility distribution
1069 system could also help ensure recovery of T&D costs without introducing demand
1070 charges. TOU energy rates, like demand charges, rely on the installation of metering
1071 capable of capturing hourly interval demand data. So, these rates will also incur higher
1072 meter costs to implement and may suggest that other intermediate steps might be
1073 preferable in the near term to address shifted costs. Division witness Dr. Artie Powell will
1074 address these steps.

1075

1076 **Q. What would you recommend regarding TOU-based energy rates?**

1077 A. TOU or other time-differentiated energy charges may more closely align NEM rate
1078 design with cost causation principles, if metering can be implemented to measure
1079 customer imports and exports separately over all hours of the billing cycle, to reflect
1080 hourly and seasonal differences in wholesale power supply costs and the peak demand
1081 periods which T&D systems are built to meet. The design of TOU or other time-
1082 differentiated rates would be informed by additional data collection and analysis to better
1083 understand the impact of such rates have sending price signals to the NEM customer so

1084 they shift their loads out of the peak, higher cost periods. Data collection through a rate
1085 pilot program(s) could enable the Commission to make more informed decisions about
1086 different time-based rate structures going forward.

1087

1088 **Q. What do you conclude regarding the use of demand charges and TOU-based rates?**

1089 A. I support the consideration of both a demand charge schedule and TOU schedule to allow
1090 for customer choice, as noted in Division Witness Dr. Artie Powell's Direct Testimony.

1091

1092 **E. Gradualism**

1093 **Q. Please explain how any rate design approved by the Commission should be adopted.**

1094 A. Regardless of the ultimate rate design and rates approved by the Commission, the rate
1095 design and rates should be gradually implemented through steps that enable proper
1096 transition to bi-directional meters and avoid or mitigate adverse average rate and bill
1097 impacts for customers. It will take time for the Company to replace or reprogram meters
1098 that capture bi-directional energy flow, proper customer outreach, and for customers to
1099 adjust to the new rate structure(s) by altering usage patterns to coincide with the change
1100 in price signals.

1101

1102 **F. Grandfathering**

1103 **Q. Did the Company address grandfathering of current NEM customers in its**
1104 **testimony?**

1105 A. No. The Company only addressed the fact that current residential NEM customers would
1106 not be placed under the proposed Schedule 5, but could voluntarily opt in if desirable.
1107 Grandfathering considerations are important because of the potential for discrimination
1108 between current versus future NEM customers. It is practical to employ grandfathering,
1109 along with gradualism, during a rate design transition process to minimize customer
1110 impacts and allow the Company to get the proper metering infrastructure and billing set
1111 up to handle a new rate design(s). After an appropriate transition period, all NEM
1112 customers could likely be subject to the same rate design.

1113

1114 Under the Utah NEM Statute, the Company must have a NEM program, but that program
1115 can be capped in size. The current cap size set by the Commission can be adjusted
1116 downwards to a lower level, which would help usher in the beginning of a transition
1117 period where grandfathering of current NEM customers can be used to help those
1118 customers adjust to a future rate design(s). In short, by decreasing the NEM program cap
1119 to a level near the current program size or a near-term projection of size, the Commission
1120 can create a defensible class of NEM customers that might be gradually transitioned
1121 while newcomers after the Commission's order in this proceeding might have a new
1122 regime immediately applied.

1123

1124 **G. Interconnection Application Fees**

1125 **Q. Please explain the interconnection application fees proposed by the Company.**

1126 A. The Company is proposing to implement a Level 1 interconnection application fee, as
1127 well as increase the current Level 2 and Level 3 interconnection application fees already
1128 in place. The interconnection application fees are charged by the Company to cover the
1129 NEM program administration and engineering costs when customers looking to add
1130 private DG apply for interconnection. These costs cover the Company's customer call
1131 center costs of handling all three levels of applications, as well as the customer
1132 generation, and engineering and operating costs of reviewing each of the applications. As
1133 the Company suggests, each level of application carries with it increasing complexity and
1134 therefore adds to the overall interconnection costs to properly integrate increasing levels
1135 of DG at any point on the system.

1136
1137 Currently, only Level 2 and Level 3 applications have been charged interconnection
1138 application fees. However, as the Company has explained "[a]pproximately eighty
1139 percent of applications reviewed are satisfied at Level 1."⁸⁷ In addition, the Company
1140 continues to experience an increasing volume of applications and is considering ways to
1141 automate the application process.⁸⁸ In support of the Company's implementation of an
1142 application fee for Level 1, it explains that California and Washington have implemented
1143 application fees for smaller systems.⁸⁹

1144

⁸⁷ Direct Testimony of Douglas L. Marx, p. 9, lines 169-170.

⁸⁸ *Id.*, p. 11, line 197, Figure 2.

⁸⁹ *Id.*, p. 12, lines 210-215.

1145 **Q. Do you agree with the Company's proposal to increase interconnection application**
1146 **fees for all three levels of application?**

1147 A. In general, I agree with the Company that there is a cost of interconnection incurred for
1148 both program administration and engineering review when a customer submits an
1149 interconnection application for any system, regardless of size. These costs should be
1150 borne only by the applicants, since non-NEM customers are not contributing to these
1151 costs. Note as well that it is standard in the electric power industry for generation
1152 developers to pay for costs to interconnect to the grid.

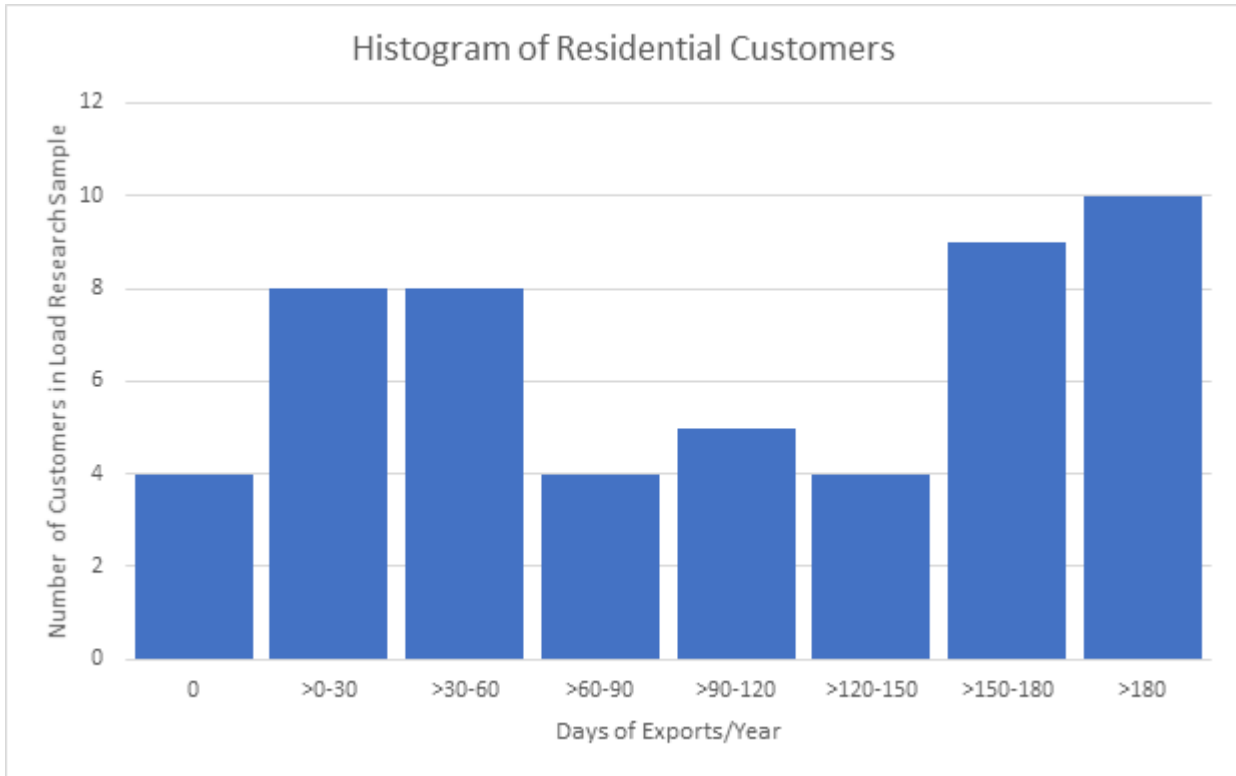

1153

1154 Because of the potential for additional costs to deal with reverse power flows, I also
1155 recommend that interconnection costs vary based on whether the interconnecting DG
1156 system is expected to export power to the grid. Based on the Company's load research
1157 results, some residential customers export most days, while others not at all. The
1158 distribution of the frequency of exports is shown in the chart below.⁹⁰

⁹⁰ See RMP response to EFCA 1.3 Attachment [CONFIDENTIAL].

1159
1160

Figure 4 – Frequency of exports of residential NEM customers based on load research study results.

1161
1162

H. Non-Residential Customers

1163
1164
1165

Q. How do the NEM Breakout ACOS results vary for residential and commercial classes?

1166
1167
1168
1169
1170

A. As shown in Table 2 previously, revenue parity ratios for commercial NEM classes were lower for Schedule 23 and Schedule 10 classes but higher for Schedule 6 and Schedule 8. For classes that had lower revenue parity ratios, the difference between NEM and non-NEM customers was not as large as with residential customers.

1171 **Q. What factors contribute to the difference in results for residential classes and**
1172 **commercial classes?**

1173 A. The difference reflects the different rate structures for these classes. Except for small
1174 customers on Schedule 23, commercial classes listed in Table 2 have demand charges and
1175 lower energy charges than residential customers. Customer maximum demand can be
1176 reduced by solar DG systems if the maximum demand level in the absence of DG occurs
1177 during daylight hours, but the amount of reduction from solar DG is limited to the
1178 difference in maximum demand during daylight hours and maximum demand in non-
1179 daylight hours. Put another way, a customer cannot fully zero out its demand charge with
1180 a solar system unless it has an energy storage system such as a battery, because demand
1181 will be placed on the grid when the solar system does not generate.

1182
1183 Lower energy charges also create a lower rate of compensation for some exports to the
1184 grid. Under current tariffs, commercial NEM customers are billed for their net energy
1185 consumed each month as long as exports to the grid are less than energy consumed from
1186 the grid. For these customers, exports are all compensated at the retail energy rate. If
1187 exports exceed energy consumed from the grid, the net credit for excess NEM generation
1188 is valued either at an avoided cost rate from Schedule 37 or a total average retail rate.
1189 Since total average retail rates are higher than avoided costs, to date commercial NEM
1190 customers have all chosen this compensation option.⁹¹ For these customers, exports then

⁹¹ Direct Testimony of Joelle R. Steward, p. 33, lines 637-638.

1191 have two different compensation rates: the retail energy rate up to the level to net out all
1192 energy consumption and then the total average retail rate for the excess.

1193

1194 The Company proposes to eliminate the option to value excess NEM credits at total
1195 average retail rates, which would lower export compensation levels significantly for
1196 customers with excess NEM bill credits.

1197

1198 **Q. Do your conclusions and recommendations regarding residential NEM customers**
1199 **also apply to commercial NEM customers?**

1200 A. Most of them do, yes. The analysis supporting placing residential NEM customers in a
1201 separate class is specific to residential customers, and the Company does not propose to
1202 place commercial NEM customers into a separate class from non-NEM customers. My
1203 other conclusions, namely on the importance of correctly valuing exports, NEM costs and
1204 benefits, and the use of application fees and interconnection fees also apply to all NEM
1205 customers.

1206

1207 **Q. Did you do any further analysis of commercial NEM customers?**

1208 A. Yes. I analyzed Schedule 23 NEM customers and their differences from Schedule 23
1209 non-NEM customers. I focused on these customers because some of them are similar to
1210 residential customers in that they do not pay demand charges and the NEM breakout
1211 ACOS results show a lower parity ratio for NEM customers in this class compared to

1212 non-NEM customers. Moreover, customer-related costs are a more significant portion of
1213 the total bill for small commercial customers compared to large commercial customers.

1214

1215 **Q. What data did you analyze for Schedule 23 NEM customers?**

1216 A. Load research for these customers was not available, but I did analyze differences in
1217 customer unit costs between NEM and non-NEM Schedule 23 customers from the NEM
1218 Breakout ACOS study.

1219

1220 **Q. How do Schedule 23 metering costs vary for NEM and non-NEM customers?**

1221 A. Based on the results in the Company's NEM Breakout ACOS, metering costs per
1222 customer are about equal for NEM and non-NEM customers, but this may be due to an
1223 error in the COS model.

1224

1225 **Q. Explain the possible error in allocating Schedule 23 metering costs.**

1226 A. It appears that RMP mistakenly uses the cost of a bidirectional meter for residential
1227 customers (\$162/meter) for allocating metering costs to Scheduler 23 customers.⁹² This
1228 cost is less than the cost of a meter for non-NEM Schedule 23 customers. If we assume
1229 NEM and non-NEM Schedule 23 customers have similar metering costs per meter, NEM
1230 metering costs would be \$238 per meter not \$162. Also, since bidirectional meters are
1231 costlier, the cost of meters for Schedule 23 NEM customers should likely be even higher
1232 than \$238.⁹³

⁹² Based on data from the Company used to create the metering cost allocator in the NEM Breakout ACOS.

⁹³ See RMP response to OCS Data Request 4.2 Attachment [CONFIDENTIAL], which discusses the kinds of meters

1233

1234 **Q. Explain the differences in customer costs between NEM and non-NEM customers**
1235 **after the rectification of the metering cost error.**

1236 A. After using an average unit cost of \$238 per meter for Schedule 23, customer unit costs
1237 for Schedule 23 NEM customers were higher than non-NEM Schedule 23 customers in
1238 all categories of customer-related costs I analyzed. This is shown in the table below.

1239 **Table 17 – Customer unit costs for Schedule 23 NEM and non-NEM customers based on**
1240 **NEM Breakout ACOS results. Assumes Schedule 23 NEM meters cost an average of**
1241 **\$238/meter.**

	SMALL COMMERCIAL NON-NEM	SMALL COMMERCIAL NEM
Services	\$3.38	\$4.54
Meters	\$1.02	\$1.63
Retail	\$1.08	\$4.17
TOTAL	\$5.48	\$10.33

1242

1243 **Q. How did Schedule 23 service drop costs change for NEM and non-NEM customers?**

1244 A. The unit cost assumptions for Schedule 23 NEM and non-NEM customers were the same.
1245 However, the NEM class had a higher proportion of 3-phase services compared to the
1246 non-NEM class, as shown in the table below. This results in an increase of costs per
1247 customer in that class because 3-phase service drops cost more than 1-phase service
1248 drops.

used for Schedule 23 customers.

1249 **Table 18 – Percentage of Schedule 23 NEM and non-NEM customers by phase service type.**

	Schedule 23 Non-NEM	Schedule 23 NEM
1-Phase	65.81%	11.80%
3-Phase	34.19%	88.20%

1250

1251 **Q. How did Schedule 23 retail costs change for NEM and non-NEM customers?**

1252 A. As with residential NEM customers, Schedule 23 NEM retail costs were higher per
1253 customer due to direct cost assignments to NEM customers. These are shown in the table
1254 below.

1255 **Table 19 – Retail function costs assigned to Schedule 23 NEM customers.**

	Schedule 23 NEM
Estimated Incremental Cost of Administration	\$16,110
Application Fee Revenue	(\$7,404)
Estimated Incremental Cost of Customer Service Cost	\$4,415
Total Incremental Cost of Administration & Customer Service	\$13,120
Total Cost/Customer/Month	\$3.35

1256

1257 **Q. Based on these results are the differences in customer-related unit costs significant**
1258 **for NEM and non-NEM small commercial customers?**

1259 A. No. Metering costs may be higher, but changes in service drop costs are driven more by
1260 other characteristics of the customers, namely larger customer size and higher frequency
1261 of 3-phase service. Additional administrative costs for the NEM program—if assigned

1262 only to NEM customers—or increased transformer costs necessary to accommodate
1263 bidirectional flows are best recovered through an alternative charge such as an
1264 application fee or interconnection fee as discussed previously in this testimony.

1265

1266 **Q. What recommendations do you make specifically regarding Schedule 23 NEM**
1267 **customers?**

1268 A. I recommend the Company clarify how the need to meter bidirectional flows would
1269 impact average per meter costs to serve Schedule 23 NEM customers compared to non-
1270 NEM customers.

1271

1272 **IV. Summary Conclusions and Recommendations**

1273 **Q. Please outline your conclusions and recommendations to the Commission.**

1274 A. Based on my analysis, I make the following conclusions and recommendations.

- 1275
- 1276 • Residential NEM customers do have a different load shape than non-NEM
1277 customers. More specifically, NEM customers exhibit the “duck curve” shape that
1278 has lower midday net consumption followed by a rapid rise in demand at sunset.
 - 1279 • Differences in load shape between residential NEM and non-NEM customers do
1280 not translate into large differences in annual load factors.
 - 1281 • There is more variation in the load factors of the residential NEM customers, but
1282 not drastically so.
 - NEM and non-NEM residential customers have similar total unit costs.

- 1283 • I do not recommend that transformer costs be included in the customer charge for
1284 residential customers. Although these costs may be fixed, that does not by itself
1285 justify their inclusion in the customer charge.
- 1286 • If there is a need for transformer upgrades to interconnect a DG system, then the
1287 cost of the upgrade is best recovered from the connecting customer through an
1288 interconnection charge and not a monthly customer charge.
- 1289 • The use of a 1NCP allocator for allocating transformer costs may double count
1290 customer loads for residential customers who switched to NEM service between
1291 July and December 2015.
- 1292 • I recommend the Company ensure that the transformer allocator does not double
1293 count customers in its NCP calculation. This should reduce costs allocated to the
1294 NEM residential class for the NEM breakout ACOS study.
- 1295 • NEM customers do require modestly higher metering costs, but that difference
1296 alone does not justify a higher customer charge.
- 1297 • Changes in service drop costs between NEM and non-NEM residential customers
1298 are driven more by other characteristics of the customers, such as placement on
1299 the underground or overhead system.
- 1300 • Based on my analysis and findings described above, it is not necessary, for now
1301 and at the current level of penetration, to separate NEM customers into their own
1302 class.

- 1303 • Despite this, I do not object to the separation of NEM customers into a separate
1304 class if deemed appropriate for other policy reasons, or to address compensation
1305 rates for excess generation exported to the grid.
- 1306 • Compensation for energy exports at retail rates is the primary driver of the low
1307 revenue parity ratio for residential NEM customers shown in the Company's
1308 NEM Breakout ACOS study.
- 1309 • Traditional NEM excess energy compensation, at full retail rates, is not
1310 sustainable in the long-run with very high rates of DG penetration.
- 1311 • All the incremental costs the Company considered for the NEM program,
1312 including administration costs, engineering costs, and integration costs appear
1313 reasonable.
- 1314 • Since the Company is using a one-year historic test-period for its cost-benefit
1315 analyses as discussed from the Phase I Commission Order, it is likely that
1316 transmission, distribution, and environmental compliance avoided cost benefits
1317 may not be able to be properly captured. Evidence of such benefits might be
1318 presented by other parties in this docket and I will respond subsequently as
1319 appropriate.
- 1320 • Avoided distribution costs would need to be analyzed over a longer period of time
1321 than one year and should also be analyzed for providing location-specific benefits
1322 when possible.
- 1323 • Avoided transmission and avoided generation capacity benefits would need to be
1324 analyzed over a longer period of time than one-year.

- 1325 • While the Company’s method to calculate avoided line losses is a reasonable
1326 proxy, it could potentially under- or over-estimate actual line losses avoided.
- 1327 • I would recommend that the Commission consider opening a separate docket to
1328 properly vet possible DG costs and benefits to RMP’s distribution system, which
1329 could potentially include parties to the current docket and all stakeholders with an
1330 interest in DG, in order to determine the compensation rate.
- 1331 • Demand charges have the potential to properly reflect cost causation on the
1332 distribution system, especially if they are based on coincident peak or are time-
1333 differentiated.
- 1334 • Due to issues regarding the installation and cost of required metering capable of
1335 recording demands over all hours of the billing cycle, customer acceptance and
1336 understanding, ability to monitor and control electricity bills, and the potential for
1337 rate shock and dislocation, I recommend demand charges be implemented
1338 gradually, if they are part of the approved rate design.
- 1339 • I recommend the Commission also consider alternative rate designs or other
1340 ratemaking tools to address problems with current rates.
- 1341 • TOU or other time-differentiated energy charges may more closely align NEM
1342 rate design with cost causation principles, if metering can be implemented to
1343 measure customer imports and exports separately over all hours of the billing
1344 cycle, to reflect hourly and seasonal differences in wholesale power supply costs
1345 and the peak demand periods which T&D systems are built to meet.

- 1346 • I support the consideration of both a demand charge schedule and TOU schedule
1347 to allow for customer choice, as noted in Division Witness Dr. Artie Powell's
1348 Direct Testimony.
- 1349 • Data collection through a rate pilot program(s) could enable the Commission to
1350 make more informed decisions about different time-based rate structures going
1351 forward.
- 1352 • Regardless of the ultimate rate design and rates approved by the Commission, the
1353 rate design and rates should be gradually implemented through steps that enable
1354 proper transition to bi-directional meters and avoid or mitigate adverse average
1355 rate and bill impacts for customers.
- 1356 • By decreasing the NEM program cap to a level near the current program size or a
1357 near-term projection of size, the Commission can create a defensible class of
1358 NEM customers that might be gradually transitioned, while newcomers after the
1359 Commission's order in this proceeding might have a new regime immediately
1360 applied.
- 1361 • I agree with the Company that there is a cost of interconnection incurred for both
1362 program administration and engineering review when a customer submits an
1363 interconnection application for any system, regardless of size. These costs should
1364 be borne only by the applicants, since non-NEM customers are not contributing to
1365 these costs.
- 1366 • I recommend that interconnection costs vary based on whether the interconnecting
1367 DG system is expected to export power to the grid.

1368 • My conclusions regarding the importance of correctly valuing exports, NEM costs
1369 and benefits, and the use of application fees and interconnection fees apply to
1370 both residential and commercial NEM customers.

1371 • I recommend the Company clarify how the need to meter bidirectional flows
1372 would impact average per meter costs to serve Schedule 23 NEM customers
1373 compared to non-NEM customers.

1374

1375 **Q. Does this conclude your testimony?**

1376 **A. At this time, yes.**
