Attorney for Utah Clean Energy

BEFORE THE PUBLIC SERVICE COMMISSION OF UTAH

<p>In the Matter of Review of Electric Service Schedule No. 38, Qualifying Facilities Procedures, and Other Related Procedural Issues</p>	<p>DOCKET NO. 14-035-140 Utah Clean Energy Exhibit 3.0</p>
--	--

Surrebuttal Testimony of Ken Dragoon
on behalf of
Utah Clean Energy

REDACTED

June 11, 2015

RESPECTFULLY SUBMITTED,
Utah Clean Energy

Sophie Hayes
Counsel for Utah Clean Energy

1 **INTRODUCTION**

2 **Q: Please state your name and business address.**

3 A: My name is Ken Dragoon. My business address is 3519 NE 15th Avenue,
4 #227, Portland, Oregon 97212.

5 **Q: Are you the same Ken Dragoon who filed direct testimony on behalf of Utah**
6 **Clean Energy in this matter on April 28, 2015 and rebuttal testimony on May**
7 **28, 2015?**

8 A: Yes.

9 **Q: What is the purpose of your surrebuttal testimony?**

10 A: The purpose of my testimony is to respond to Mr. Peterson's rebuttal
11 testimony on behalf of the Division of Public Utilities (DPU or Division), Mr.
12 Hayet's rebuttal testimony on behalf of the Office of Consumer Services (Office
13 or OCS) and Mr. Link's rebuttal testimony on behalf of Rocky Mountain Power
14 (Company or RMP), collectively referred to herein as the Parties. My testimony
15 here clarifies some mischaracterizations and misperceptions of my earlier direct
16 and rebuttal testimony.

17 In their testimony, the parties focused on the incorrect hypothesis
18 proffered by my earlier testimony regarding the origin of wintertime loss of load
19 events and argued against positions *UCE did not take* regarding splitting the
20 PacifiCorp system, excluding regions or time periods from the capacity
21 contribution analysis, and making "arbitrary" changes to maintenance schedules.
22 Rather than taking these position, my testimony sought, and continues to seek,
23 explanations for unusual and potentially anomalous results from the PaR study

24 that neither NREL nor DPU investigated. Given that the PaR results are a key
25 variable input into the capacity value calculation it is critical that we carefully
26 analyze the PaR results.

27 PacifiCorp's capacity value calculations using the CFAM method rely on
28 two main inputs: 1) the characterization of wind and solar resources, which is not
29 disputed in this docket, and 2) the results from the PaR model. The results from
30 the PaR analysis are a key variable input into the CFAM analysis and, as I've
31 discussed in my direct and rebuttal testimony, these PaR results give the
32 Company lower capacity values than other sunny, summer-peaking utilities. The
33 Commission deserves a plausible explanation for these results.

34 If the Commission wants fair and accurate capacity values for wind and
35 solar resources, then it is critical to carefully analyze and understand these PaR
36 results before approving the output of the CFAM method. The fact the model
37 calculates high numbers of loss of load events during relatively lower-load April
38 and winter months, that the Company appears not to have counted all the loss of
39 load events calculated by the model, and the as-yet unexplained reason the model
40 shows significant loss of load events in Wyoming, all raise questions about the
41 results that deserve a credible response. These questions should be answered
42 before approving capacity values for wind and solar based upon these results.

43 In this surrebuttal testimony, I strive to clarify points from my direct and
44 rebuttal testimony and to state UCE's recommendations to the Commission.

45

46 **RESPONSE TO REBUTTAL TESTIMONY**

47 **Q: Please summarize the issues you will address in your rebuttal testimony.**

48 A: Both the Company and DPU correctly observe that the hypothesis offered
49 in my direct testimony, that the wintertime loss of load events were due to
50 transmission constrained events occurring on the west side of PacifiCorp's
51 system, proved to be incorrect. I agree that this was not the cause, as the model
52 output data shows that nearly *all* of the wintertime loss of load events occurred in
53 Northeast and Southwest Wyoming.

54 While my original hypothesis on the reason for wintertime loss of load
55 events was wrong, the bigger question remains: has the PaR model correctly
56 calculated those events? Mr. Hayet's rebuttal testimony shows that although
57 PacifiCorp's total peak *loads* are approximately 1,500 MW higher in July than
58 they are in February, the number of February *loss of load events* is higher than in
59 July. Somewhat alarmingly, this does not seem to concern any of the parties,
60 despite the acknowledgement that the tool used to arrive at them is a "black box."

61 The purpose of our intervention in this matter is to understand whether and
62 how it makes sense for the Company's summer-peaking, relatively sunny climate
63 to have such relatively lower solar capacity values than other studies have
64 concluded. Specifically, I address three broad issues raised in rebuttal:

65 1. Our direct testimony conjecture with respect to wintertime outages,
66 and the need to better understand the Wyoming outages (loss of
67 load event count & Wyoming issues).

- 68 2. The misperception of our testimony with respect to splitting
69 PacifiCorp's system and excluding certain time periods.
- 70 3. The relative importance of April loss of load events and their
71 effects on the calculation.

72 ***Wintertime Outages***

73 **Q: Why are winter outages a focus of your testimony?**

74 A: Although the Office's testimony (Hayet at 183-184) refers to my apparent
75 "desire to eliminate all wintertime loss of load events" from the capacity
76 contribution analysis, my specific purpose was to illustrate the importance of the
77 winter events to the capacity value calculation and to understand whether they
78 were correctly calculated.

79 Thus, my direct testimony examined the effects of the wintertime loss of
80 load events on the solar capacity value computation, and showed that winter loss
81 of load events are the *proximate reason* for the Company's solar capacity value
82 being lower than the calculations of solar capacity values from other summer-
83 peaking systems with a good solar resource.

84 My direct testimony also raised questions about the derivation of the
85 unexpected number of spring and winter loss of load events. For example, I could
86 not reproduce the Company's *count* of the loss of load events. And I continue to
87 struggle with why, if demand is greater in summer, the Company's analysis shows
88 that loss of load events are greater in winter.

89 **Q: Please respond to the Parties' contention that the wintertime loss of load**
90 **events did not predominantly occur on the west side of PacifiCorp's system.**

91 A: The Parties' rebuttal testimony argues that the model does not show a
92 preponderance of low of load events on the west side. (Peterson at 93-109, 150-
93 163; Hayet at 184-185, 196-196; Link at 133-145). I agree with their assessment
94 that my original conjecture was not correct. As a result, the issues I raised about
95 the appropriateness of the Company's application of CFAM to constrained
96 systems (e.g., Link at 61-69) are not relevant unless transmission constraints to
97 Wyoming are a major factor in the analysis.¹

98 It is unclear whether transmission congestion is the cause of the
99 wintertime loss of load events that occur predominantly in Northeast and
100 Southwest Wyoming, as the Company has not provided transmission congestion
101 data.²

¹ With regard to the relevance of transmission congestion in CFAM analysis: as I discussed in my direct testimony, CFAM was developed to compare the efficacy of renewable resources in meeting load compared with traditional resources. To wit, if a loss of load event could not be reduced by a *traditional resource* due to transmission congestion, it would not be accurate to reduce the capacity value of a renewable resource by including that loss of load event in the CFAM calculation. Logically, you would need to reduce the capacity value of all resources that are not able to meet load due to transmission constraints. My original proposition was to exclude specific loss of load events in the CFAM calculation that resulted from transmission congestion, not exclude specific regions, or time periods, or to split the PacifiCorp system, as I will discuss more below. If the bulk of the loss of load events arise in transmission constrained areas of the grid, the overall capacity value of renewables should not be penalized as no resource, fossil or otherwise, outside of a transmission constraint will have much value toward meeting load past the constraint.

² Utah Clean Energy has asked a series of data requests in an attempt to get to the bottom of this issue, and is currently awaiting answers to our fourth set.

102 **Q: Does your admission that your conjecture about the cause of wintertime loss**
103 **of load events being incorrect lend weight to the Company's analysis?**

104 A: Not necessarily. In my view, the finding only deepens the mystery of the
105 wintertime loss of load events. The purpose of the original conjecture was to
106 construe a reason for the relatively high number of loss of load events in the
107 *winter* for the Company's *summer* peaking system. The most likely cause that I
108 could think turned out not to be the cause. As a result, the mystery has only
109 deepened. Only the Office ventured an explanation for the result.

110 **Q: What was the Office's explanation for the relative abundance of wintertime**
111 **loss of load events?**

112 A: Hayet's rebuttal testimony (at 201-215) offers the explanation that the
113 Wyoming outages are due to the seasonal shape of Wyoming's load. Given that
114 winter and summer peak loads are similarly high in Wyoming, he posits that it is
115 reasonable to expect that the loss of load events in winter and summer would be
116 roughly equal.

117 **Q: Is that a reasonable explanation of the PaR results?**

118 A: It is a difficult explanation to accept because the State of Wyoming
119 contains many times as much generation as peak load. For there to be load in
120 excess of generation in Wyoming, a significant fraction of Wyoming's generation
121 would need to be out of service, causing shortages throughout PacifiCorp's entire
122 system—not just in Wyoming.

123 Alternatively, it could be that transmission limits generation available in
124 other parts of PacifiCorp's system from reaching the NE and SW Wyoming areas.

125 **Q: What could be the cause of the PaR model output showing a preponderance**
126 **of April and wintertime loss of load events occurring in Wyoming?**

127 A: It isn't clear to me, but is likely embedded in the PaR modeling logic. In
128 my opinion, the fact that the outages occur in *Wyoming* is likely due to PaR
129 modeling logic or transmission constraints serving those areas of Wyoming. If the
130 cause is transmission, the calculated solar capacity values are largely relevant
131 only compared with conventional generation located in Wyoming. No resource,
132 fossil or otherwise, that is outside of those areas would be able to address those
133 loss of load events. This is simply a question of physics. Again, it is important to
134 understand what is causing the loss of load events in order to validate the CFAM
135 results.

136 **Q: Is it important to understand the loss of load events in Wyoming when**
137 **considering whether the CFAM analysis is accurate?**

138 A: Yes, absolutely. A summary of the Company's responses to OCS data
139 request 3.10-3 (parts 1-5) that I provided in my direct testimony shows 718 loss of
140 load events in Northeast and Southwest Wyoming alone. As discussed in my
141 direct and rebuttal testimony, the Company counts just 715 events in the CFAM
142 analysis for the entirety of its system (Company workpaper "Hourly LOLP
143 2017.xlsx"). We don't yet understand why there appears to be a discrepancy
144 between their workpaper and data request response.

145 Nearly half of the Wyoming loss of load events (295) occur in April and
146 87% (626 events) occurred between November and April (in the Northeast and
147 Southwest areas of Wyoming). Given that the winter and spring events in

148 Wyoming appear to be the key events and inputs into the CFAM analysis, it is
149 critical to understand the validity and applicability of these results if the desired
150 outcome is an accurate capacity value.

151 **Q: Do you know which of the 718 loss of load events that occurred in Wyoming**
152 **are included in the CFAM analysis?**

153 A: No. As discussed below, I could not match the number of events from the
154 PaR model to the number of events used in the CFAM calculations, even after
155 removing the Colorado events discussed in my rebuttal testimony.

156 **Q: Is the issue with matching the Company's loss of load count related to the**
157 **Colorado loss of load events?**

158 A: Not directly. The Office argues (Hayet at 171-182) that the Company
159 reasonably explained its logic for not counting the Colorado events. While I agree
160 with that, my own count of remaining loss of load events, based on the
161 Company's data response to OCS 3.10, is substantially higher than the
162 Company's "Hourly LOLP 2017.xlsx" workpaper. The Company may have had
163 reasons for eliminating other loss of load events—events outside of Colorado;
164 however, despite data requests, this mismatch in the number of loss of load events
165 remains.

166 **Q: Are there other reasons to question the validity of the PaR wintertime loss of**
167 **load results?**

168 A: Perhaps the clearest illustration of the why the wintertime loss of load
169 events merit closer scrutiny is in the Office's testimony (Hayet, Figure 1 at 191
170 and Figure 5 at 278). Figure 1 shows February loss of load events as

171 approximately equal to those in July, while Figure 5 shows that July loads are
172 roughly 1,500 MW higher. All else being equal, the higher loads would be
173 accompanied by higher numbers of loss of load events. While these results are not
174 impossible, given that DPU approached the PaR analysis as a “black box” and
175 NREL did not comment on the assumptions or results of the model, it is
176 appropriate to seek an explanation for this result before blindly concluding that it
177 is reasonable.

178 ***Splitting PacifiCorp’s System and Excluding Time periods***

179 **Q: Does your testimony advocate splitting PacifiCorp’s system and excluding**
180 **specific time periods from the CFAM computation?**

181 A: Contrary to the Parties’ contention (Peterson at 129-130; Hayet at 311-
182 312; Link 205-218), I did not intend to suggest that PacifiCorp’s system be split
183 for the purpose of this analysis or otherwise, nor to categorically exclude specific
184 time periods. My original testimony suggested not counting loss of load events
185 that occurred either because of transmission congestion, or other potentially errant
186 artifacts of modeling (e.g., maintenance schedule assumptions).

187 The purpose of removing the winter and April loss of load events was
188 intended to show the *effect* of those events on the calculated result. [REDACTED]

189 [REDACTED],
190 not to argue for categorically excluding April from the analysis.

191 ***Maintenance Schedules***

192 **Q: Is it appropriate for the Company to consider changes to the modeled**
193 **maintenance schedules?**

194 A: The vehemence of the Parties' objection to any consideration of the
195 assumptions relating to maintenance schedules (Peterson 68-73, 79-81, 81-83;
196 Hayet 256-260, 264-296; Link 188-197) was very surprising to me. The Parties
197 argue variously that the maintenance schedule is optimized to minimize ratepayer
198 exposure to power costs; any change to the assumption would be arbitrary;
199 changing the maintenance schedule would only move loss of load events to a
200 different time period; and that there is no evidence to suggest changing the
201 maintenance schedules would have any effect ██████ loss of load events. I
202 dispute each of these arguments, and affirm that each of them is incorrect.

203 **Q: Why do you contend that the modeled maintenance schedule is not**
204 **optimum?**

205 A: Every year has a different maintenance schedule—for example some
206 power plants only require major maintenance every two years. So the modeled
207 schedule cannot be “optimized” for anything but 2017—certainly not for each of
208 the years over which the Company will receive a capacity value from solar plants.
209 So even if you believe that the maintenance schedule is optimized for 2017, it is
210 certainly not optimized for any of the years during the resource deficiency period,
211 long after 2017 is over.

212 The maintenance schedule is also not optimized for additional renewable
213 resources for which this study will be used to evaluate. Furthermore, a casual

214 glance at the actual data would make most people question whether it is truly
215 optimized, even for 2017. There are zero megawatts of maintenance planned

216 [REDACTED]

217 [REDACTED] One must postulate an enormous and unrealistic power price differential
218 between the [REDACTED] to believe that it is
219 optimized based on price alone.

220 I understand that there are other factors to optimize over, but all of the east
221 side maintenance begins exactly [REDACTED] Further, when you look at
222 Figure 1, below, you see that [REDACTED] have [REDACTED]
223 [REDACTED] more outages than the remainder of the month and account for nearly a
224 third of the April loss of load events. It is possible that staggering some of the
225 shorter maintenance [REDACTED]
226 [REDACTED] could sharply reduce the [REDACTED] loss of load events.

227 Figure 1 demonstrates the sensitivity of the CFAM method to maintenance
228 assumptions.

229

Figure 1.

230

231 **Q:** What evidence is there for your statement that moving [REDACTED]

232 [REDACTED]

233 [REDACTED]

234 **A:** The largest loss of load [REDACTED]. That
235 strongly suggests that moving just a single generator's maintenance schedule
236 assumption would be sufficient to reduce a significant number of the model's loss
237 of load events.

238 **Q:** Isn't changing the maintenance schedule assumption arbitrary?

239 **A:** No. Spreading out maintenance a bit more reasonably is not nearly as
240 arbitrary as [REDACTED]

241 [REDACTED]

242 **Q: Would moving the maintenance schedule cause the model to simply switch**
243 **loss of load events from one month or time period to another?**

244 A: [REDACTED]
245 [REDACTED]. Moving some of the maintenance from an overly-stressed
246 maintenance month to a more surplus month would not increase the loss of load
247 probability in the target month appreciably if the change is modest compared to
248 the surplus. It is possible that there could be some additional loss of load events,
249 but the loss of load events in [REDACTED]
250 [REDACTED] would register many, or
251 even any, increase in events. In any case, this can be tested by rerunning the
252 model with a modest maintenance schedule change.

253 **Q: Would a change to the maintenance schedule increase replacement power**
254 **costs?**

255 A: First, it appears that moving the start of just one or two maintenance
256 schedules from one [REDACTED] could be enough to
257 avoid many of the loss of load events. So, in order to believe that changing the
258 maintenance schedule would increase power costs, you need to believe that not
259 only [REDACTED] power prices the lowest of the year, you must believe that prices [REDACTED]

260 [REDACTED], are the lowest of the year.³ Second, if PacifiCorp does focus
261 its east side maintenance [REDACTED] becomes short, as this study suggests, it
262 could have the result of sending the market signals that could result in increased
263 prices. Because prices tend to rise when shortages occur, causing a large shortage
264 could send a sufficient market signal to cause prices to rise temporarily.

265 ***Recommendations***

266 **Q: Please summarize your recommendations for the Commission**

267 A: The Parties conclude (Peterson 187-189, Link 13-15) that the result of the
268 CFAM calculations is reasonable. Since DPU does not question the output or
269 inputs of the PaR model, their conclusion hinges on an assessment that the
270 Company's results are within a zone of reasonableness at levels of solar
271 penetration near the expected level on PacifiCorp's system (Peterson direct at
272 179-183). However, the Company's testimony (Link at 234-236) states that their
273 study assumed 579 MW of solar, which would produce less than 2% of
274 PacifiCorp's *energy* load.

[REDACTED]

275 A more appropriate comparison of the Company's proposal is based on
276 the 0-2% region of Figure 1, not the 5% level, as the chart that the DPU refers to
277 *is based on energy, not capacity.* (Peterson Direct Figure 1 at 171 *et seq*).

278 The Company's results therefore fall out of the zone of reasonableness
279 using the DPU's standard. I recommend a third party review of the PaR modeling
280 assumptions and results before approving the Company's proposed solar capacity
281 value. The Commission should not accept or approve the Company's solar
282 capacity values until questions about the anomalous results of the PaR model and
283 the applicability of certain PaR results from anomalous regions are addressed by a
284 third party.

285 **Q: Do you have any changes to the recommendation that you put forth in your**
286 **rebuttal testimony?**

287 A: Yes. In speaking with some of the parties it became clear to me that they
288 were very concerned with the current capacity value for solar used in the avoided
289 cost methodology. I recommend the following to address this concern: the
290 Commission should revise its interim solar capacity values while anomalous PaR
291 results are investigated. One option would be to assign solar capacity values that
292 are half way between current values of 68% and 84% and the Company's
293 proposed 34.1 and 39.1% until the third party analysis is completed.

294 **Q: Does that conclude your testimony?**

295 A: Yes.
