RE: **Docket No. 17-035-61 – In the Matter of the Application of Rocky Mountain Power to Establish Export Credits for Customer Generated Electricity**

Pursuant to the Phase I Scheduling Order and Notice of Hearing, and Notice of Phase II Scheduling Conference, Rocky Mountain Power (the “Company”) hereby submits for filing its proposed load research study plan.

The Company respectfully requests that all formal correspondence and requests for additional information regarding this filing be addressed to the following:

By E-mail (preferred): [datarequest@pacificorp.com](mailto:datarequest@pacificorp.com)  
[utahdockets@pacificorp.com](mailto:utahdockets@pacificorp.com)  
[Jana.saba@pacificorp.com](mailto:Jana.saba@pacificorp.com)  
[Yvonne.hogle@pacificorp.com](mailto:Yvonne.hogle@pacificorp.com)

By regular mail: Data Request Response Center  
PacifiCorp  
825 NE Multnomah, Suite 2000  
Portland, OR 97232

Informal inquiries may be directed to Jana Saba at (801) 220-2823.

Sincerely,

A handwritten signature in blue ink that reads "Joelle Steward".

Joelle R. Steward  
Vice President, Regulation

Rocky Mountain Power  
Docket No. 17-035-61  
Witness: Kenneth Lee Elder, Jr

BEFORE THE PUBLIC SERVICE COMMISSION  
OF THE STATE OF UTAH

ROCKY MOUNTAIN POWER

---

Direct Testimony of Kenneth Lee Elder, Jr

February 2018

1 **Q. Please state your name, business address and position with PacifiCorp.**

2 A. My name is Kenneth Lee Elder, Jr. My business address is 825 NE Multnomah  
3 Street, Portland, Oregon 97232. My position is Manager, Load Forecasting. I am  
4 testifying on behalf of Rocky Mountain Power, a division of PacifiCorp (“the  
5 Company”).

6 **Q. Please describe your education and professional experience.**

7 A. I have a Bachelor’s Degrees in Agriculture Business from Tarleton State University  
8 and a Master’s Degree in Agricultural and Resource Economics from Colorado State  
9 University. I have been with PacifiCorp for over a year, where I have managed load  
10 research and load forecasting activities. Before joining PacifiCorp, I was an  
11 economist for a natural resource consulting firm for eight years.

12 **Q. Please describe the responsibilities of your current position.**

13 A. I am responsible for the development of all customer class load-profile estimates used  
14 for cost allocation, rate design, forecasting, and special studies. I direct the design,  
15 implementation, and maintenance of all load studies performed at PacifiCorp. I am  
16 also responsible for developing the Company’s long-term load forecast.

17 **PURPOSE AND SUMMARY OF TESTIMONY**

18 **Q. What is the purpose of your testimony?**

19 A. My testimony provides an overview of load research, load research processes as they  
20 apply to the development of customer-class loads, and the Company’s proposed plan  
21 to develop load information for use in this docket.

22 **Q. Please summarize your testimony.**

23 A. My testimony describes the Company’s proposed load research study to collect

24 profiles for energy delivered from the grid to the customer and energy exported from  
25 the customer to the grid. This data is necessary to calculate the value of energy  
26 exported from private generation (“PG”). To further supplement the body of data  
27 available and to better understand the intertemporal relationship between PG,  
28 delivered energy, exported energy, and full requirements energy, the Company  
29 proposes a study of PG. My testimony describes why the design of the PG study is  
30 reasonable and is consistent with industry standards.

31 **BACKGROUND**

32 **Q. Can you please provide a brief summary of the purpose of the export credit**  
33 **proceeding?**

34 A. Yes. In the docket to investigate the costs and benefits of the Company’s net  
35 metering program, Docket No. 14-035-114, (“NEM Docket”), the parties entered into  
36 a settlement which grandfathered net metering customers under Tariff Schedule 135  
37 as of November 15, 2017, and established a new transition program (“Transition  
38 Program”) for customer generators. The settlement also required an export credit  
39 proceeding to determine the compensation rate for exported power from customer  
40 generation systems, including all customers after the expiration of the grandfathering  
41 period and transition period for customers on Schedules 135 and 136.

42 **Q. How is the export credit proceeding structured?**

43 A. Consistent with the Stipulation in the NEM Docket, the Export Credit Proceeding has  
44 a procedural schedule that will allow for its conclusion no later than three years after  
45 initiation, which was December 1, 2017. The procedural schedule is bifurcated into  
46 two phases, Phase One will determine the load research study plan and Phase Two

47 will determine the export credit rate that will be paid to customer generators on the  
48 transition program. In this filing, I present the Company's proposed load research  
49 study as part of Phase One.

### 50 **LOAD RESEARCH STUDY OVERVIEW**

51 **Q. What is the general purpose of load research?**

52 A. Load research gathers the data needed to study customer usage so the Company can  
53 effectively allocate costs, design rates, plan for load, appropriately size transformers  
54 and distribution circuits, and enhance customer service. Most demand-related costs  
55 for production, transmission, and distribution facilities can be allocated to classes of  
56 customers based on system peaks, class peaks, or individual customer demands that  
57 are determined from load research data.

58 Load research studies are designed to provide information on rate-related  
59 activities such as demands associated with specific customer classes at specific peak  
60 periods. These loads are derived by either direct measurement, when all customers  
61 associated with a particular rate group have load-profile meters installed, or by  
62 sampling for rate groups where customers do not have load-profile meters.

63 **Q. Please provide a brief overview of load sampling.**

64 A. There are a wide range of sampling options available for estimating load-profile  
65 characteristics, from simple random sampling to more elaborate model-based  
66 sampling procedures. The two most widely accepted sampling options used within the  
67 electric industry are simple-random sampling and stratified-random sampling.

68 Simple-random sampling means that each customer in the sample has the  
69 same probability of being selected. The method offers relative ease of use and the

70 sampling is considered to be the most representative of the sample population.  
71 However, simple-random sampling has larger errors from the same sample size than  
72 stratified-random sampling. Therefore, in load research studies, simple-random  
73 sampling is used mainly for populations with relatively few customers or for when  
74 the population has similar characteristics.

75 Stratified-random sampling divides the sample, or customer class, into sub-  
76 classes that have like characteristics. The technique has the effect of reducing the  
77 overall variance of the class, thus reducing sample size. Stratified-random sampling is  
78 a widely used and accepted technique because the statistical precision of a sample can  
79 usually be improved by using stratification. Therefore, a smaller sample size can be  
80 used with the same degree of precision.

81 **Q. What sampling methodology is used by the Company?**

82 A. All samples designed and installed in the Company's Utah service territory are based  
83 on stratified-random samples using a systematic random-sampling approach, and the  
84 designs meet or exceed the standard specified in 1978 by Section 133 of the Public  
85 Utilities Regulatory Policy Act ("PURPA"). The specific parameters of the sample  
86 design are outlined in the Code of Federal Regulations ("CFR"), Title 18, Chapter 1,  
87 Subchapter K, Part 290.403, Subpart B, which states:

88 **Accuracy Level.** If sample metering is required, the sampling method and  
89 procedures for collecting, processing, and analyzing the sample loads, taken  
90 together, shall be designed so as to provide reasonably accurate data  
91 consistent with available technology and equipment. An accuracy of plus or  
92 minus 10 percent at the 90 percent confidence level shall be used as a target  
93 for the measurement of group loads at the time of system and customer group  
94 peaks."

95 The PURPA specification has become a load research standard, particularly

96 for samples that will be used to support the development of rates or other regulatory  
97 requirements.

98 **Q. Is stratified sampling a generally accepted practice for these types of studies?**

99 A. Yes. Stratified sample design is an industry-accepted practice which provides for the  
100 installation of dramatically fewer sample points to achieve target precision and  
101 confidence levels. In its July 2002 Report to the Utah Public Service Commission, the  
102 Load Research Working Group, in referencing the Company's stratified-sample  
103 designs, concluded that "techniques used by the Company to develop the load  
104 research sample design are appropriate. The load research protocol is designed to  
105 produce a sample that is accurate within  $\pm 10$  percent on 90 percent of the  
106 observations." Participants of this group included representatives of the Company, the  
107 Division of Public Utilities, the Committee of Consumer Services (of the Office of  
108 Consumer Services), Commission Staff, Crossroads Urban Center, Hill Air Force  
109 Base, Salt Lake Community Action Program, and the Utah Farm Bureau.

110 **Q. Is systematic random sampling an accepted practice for these types of studies?**

111 A. Yes. The Company employs systematic random sampling because it is a method that  
112 best ensures an even distribution across the entire population from which sample  
113 points are drawn. This provides a better representation of the population using a  
114 smaller sample size.

115 **Q. Please explain how systematic-random sampling is used in the Company's  
116 proposed load research study?**

117 A. In systematic-random sampling, the population is divided into groups. Each group  
118 contains a certain number of customers. One customer from each group is randomly

119 chosen. For example, if the population consisted of 300 customers and was rank  
120 ordered and then divided into 30 groups, each group would consist of 10 customers,  
121 and selecting one customer from each group would yield a sampling population of  
122 30 customers.

123 When selecting one customer from each group, the systematic-sampling  
124 method always selects the customer with the same relative position within each  
125 group. For example, with a group size of 10, if the random position selected is eight,  
126 then the eighth customer from each of the 30 groups is selected for inclusion in the  
127 sample. Unlike simple-random sampling, systematic-random sampling allows for an  
128 even distribution across the entire population from which sample points are drawn,  
129 providing a better representation of the population.

### 130 **LOAD RESEARCH STUDY PLAN**

131 **Q. What data will be derived from the Company’s proposed load research study for**  
132 **use in this proceeding?**

133 A. The Company’s proposed load-research study consists of three distinct components:  
134 1) a census of transition program customer-exported energy, 2) a census of transition  
135 program customer-delivered energy, and 3) a sample of PG system-energy production  
136 from grandfathered net energy metering (“NEM”) customers. Please refer to Exhibit  
137 RMP\_\_\_(KLE-1), which includes the Company’s study plan for the proposed  
138 customer generator load-research study.

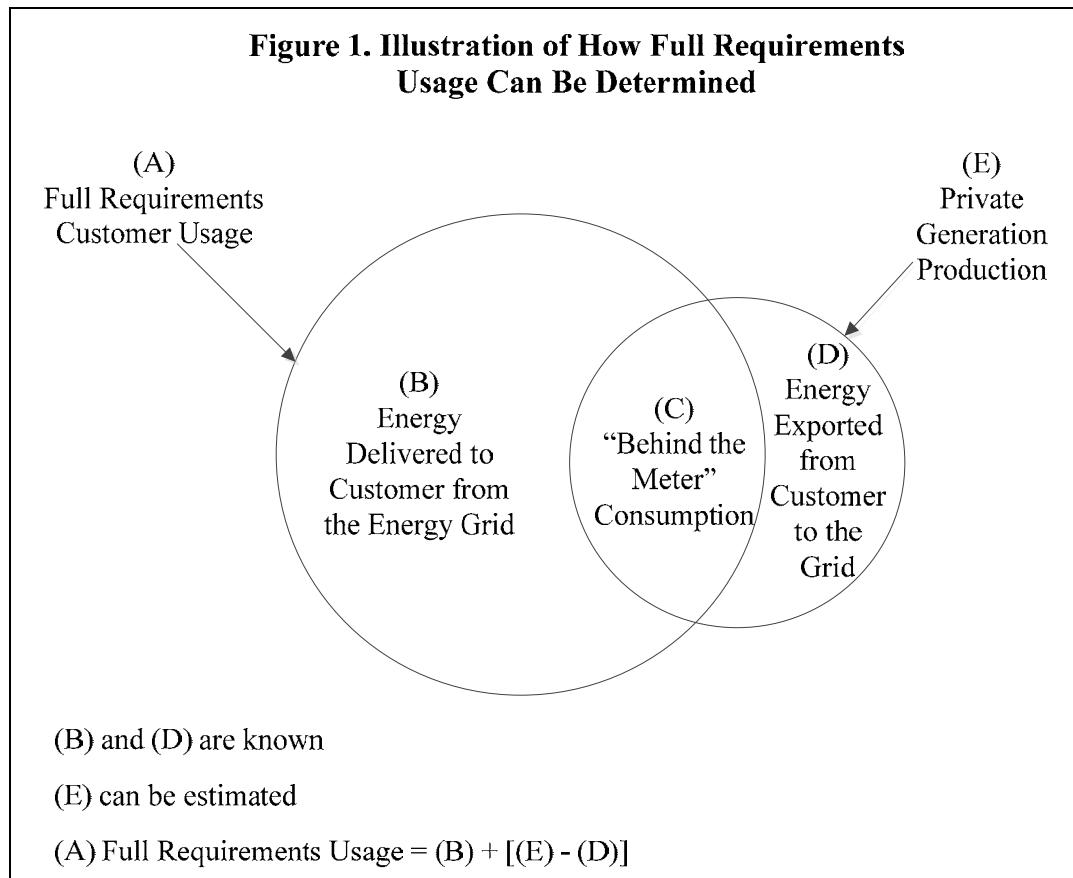

139 **Q. Why does the load-research study proposed for this proceeding individually**  
140 **consider private generation customer exports, deliveries, and generation?**

141 A. As provided in Figure 1, in order to determine PG customer usage, or full

142 requirements (A) and behind-the-meter consumption (C), the Company must have  
143 customer exports (D), deliveries (B) and PG production (E). Results from the  
144 proposed generation sample design will be used to estimate (E) and develop the  
145 missing data (C and A).

146

147 **Q. How can the data for either full requirements (A) or behind-the-meter**  
148 **consumption (C) be used to develop rates for customers?**

149 A. Understanding the relationship between a customer's usage and PG with exported and  
150 delivered energy can be useful for identifying differences by rate class as well as  
151 intra-class differences that vary with the level by which a customer offsets its load  
152 requirements with PG. This information could be useful in the future for rate setting  
153 purposes.

154 **Q. How does the Company propose to obtain a census of transition program**  
155 **customer exports and deliveries?**

156 A. The Company has established a process to obtain 15-minute interval export and  
157 delivery data for each transition customer given that each transition customer will be  
158 billed and credited by the Company based on 15-minute intervals. At this time,  
159 thirteen transition-program meters have been installed and 15-minute interval export  
160 and delivery data is being collected by the Company.

161 **Q. Is the purpose of the generation sample different to other customer-based load**  
162 **research samples?**

163 A. Yes. Normally the goal of a load-research sample is to install a meter that directly  
164 measures the 15-minute usage of a particular set of customers. Given that usage for a  
165 PG customer is not directly measurable, it is necessary to design a study that allows  
166 for the calculation of customer usage (as illustrated in Figure 1). Therefore, the  
167 purpose of the generation sample is not to directly measure the differing usage  
168 patterns of a customer; rather, its purpose is to measure the output of a solar panel  
169 array so that this value can be used to better understand the intertemporal relationship  
170 between exported, delivered, and full-requirements usage.

171 **Q. Are there any differences between the design of the generation sample and other**  
172 **customer-based load research samples that the Company has conducted?**

173 A. Yes. Typically, load research samples are designed based on billed energy. For the  
174 proposed PG study, the Company proposes a sample design based on PG nameplate  
175 capacity.

176

177 **Q. Why does the generation sample design rely on nameplate capacity?**

178 A. The generation sample is not intended to directly measure the differing usage patterns  
179 of a customer, or (A) as identified in Figure 1. The generation sample is intended to  
180 measure the output of a solar panel array, or (E) as identified in Figure 1. Therefore,  
181 the variable of interest with regard to the generation sample is PG system-energy  
182 production.

183 Ideally, a population should be stratified by the variable of interest, in this  
184 case this variable would be PG system-energy production. However, when the  
185 variable of interest is not known, as in this case, an auxiliary variable that is highly  
186 correlated with the variable of interest should be used. As such, PG system-nameplate  
187 capacity was determined to be the best variable to use for sample design because it is  
188 highly correlated with solar system energy production. A highly correlated auxiliary  
189 variable enables accurate strata definition and assignment of units to the proper strata.

190 **Q. Is it appropriate to use the 36 existing generation profile meters used in a  
191 previous study for the proposed generation sample?**

192 A. Yes. The proposed PG sample for this filing calls for a total of 70 sample sites, of  
193 which 36 generation-profile meters were previously used for the load-research study  
194 conducted in the NEM Docket. For that research, the Company randomly selected  
195 these 36 meters based on billed energy to identify energy production from NEM  
196 customers.

197 The Company proposes to re-stratify these 36 generation-profile meters based  
198 on their nameplate capacity, rather than billed energy, and utilize these meters for the  
199 proposed research to manage resources efficiently.

200           It is a standard practice for utilities to conduct a sample rotation for a load-  
201 research sample after it has been in place for several years. In continuous load-  
202 research studies, sample rotation is necessary to keep the sample current with the  
203 changing utility population. Sample rotation requires the utility to check the currently  
204 installed sample against the current population. This process requires that a new  
205 sample be designed and compared against the existing sample. If warranted by  
206 changes in the overall population, the Company will supplement the number of  
207 interval meters called for in the initial sample design, or replace the sample.

208 **Q. Does the Company have any concerns using export and delivery data from**  
209 **transition program customers and generation data based on a sample of**  
210 **grandfathered NEM customers to calculate full requirements?**

211 A. No. As previously noted, the Company will acquire a census of export and delivery  
212 data from Schedule 136 customers, whereas the generation sample will be based on  
213 Schedule 135 customers. Exports and deliveries are affected by behind-the-meter  
214 consumption; whereas, generation is not typically impacted by customer-usage  
215 patterns. The purpose of the generation sample is to measure the output of a solar  
216 panel array. In general, solar panel production is fairly predictable, and the Company  
217 believes that private-generation-system output will be similar between Schedule 135  
218 and Schedule 136 customers.

219 **Q. Does the generation sample incorporate geographic location into the design?**

220 A. Yes. As provided in Exhibit RMP\_\_(KLE-1), the Company determined the  
221 minimum size for the proposed sample to be 54. A random selection process was  
222 used to ensure enough systems within each county of Utah were selected in the

223 proposed sample so that it was representative of the overall saturation of rooftop-solar  
224 installations within each county in Utah. In order to achieve a geographically  
225 representative sample, the Company is proposing to use an oversampling approach  
226 where the sample would include 70 sites. Exhibit RMP\_\_\_\_(KLE-1) provides the  
227 geographic location of the proposed sample and its relationship to currently installed  
228 private-generation systems.

229 **Q. Does the generation sample specifically incorporate system orientation and tilt**  
230 **into the design?**

231 A. No. The Company has numerous concerns with designing a multi-dimensional  
232 sample that specifically accounts for orientation and tilt. For example, the Company  
233 has PG orientation and tilt data available for 10,309 customers or 42.8 percent of the  
234 current PG customer population (24,082 customers). Therefore, it would be necessary  
235 for the sample to be based on a subset of the entire population of private-generation  
236 customers in Utah. Furthermore, of the 10,309 customers with orientation and tilt  
237 data, 2,555 have multiple panel arrays with varying orientations. The Company data  
238 contains capacity only at the household level, not by each customer's individual solar  
239 panel array. Therefore these 2,555 customers cannot be incorporated into the sample.  
240 Eliminating these additional customers would further reduce the sample size to  
241 represent 32.2 percent of the PG customer population.

242 **Q. What level of confidence is incorporated into the Company's proposed sample**  
243 **design?**

244 A. Based on informal discussions with the interested parties in this docket, the accuracy  
245 of the generation sample design was increased to achieve a minimum accuracy of

246 plus or minus 10 percent at the 95 percent confidence level. This increased the  
247 proposed sample size from 62 sites to 70 sites.

248 **Q. Please describe the data collected in these load studies.**

249 A. Load-research participants have specialized profile metering installed at the site.  
250 These meters record exported energy, delivered energy, and PG system production in  
251 sub-hourly increments for the duration of the load study (96 intervals/day/meter,  
252 2,880 intervals/30-day month/meter, 35,040 intervals/year/meter). Because these  
253 meters record and store time-differentiated data, the Company is able to determine  
254 exported, delivered, and production for any identified date and time (system,  
255 jurisdictional, and class peaks). Along with a sample of customers who will have  
256 profile meters that measure their private-generation output, the Company will have  
257 profiles of exported and delivered energy for all customer generators on the transition  
258 program. Ultimately, this census data from transition-customer generators will be the  
259 basis for determining the value of exports.

260 **Q. Which Utah Schedules have load profile metering installed?**

261 A. At the present time, there are 100 profile meters installed on Schedule 6 customers,  
262 130 profile meters installed on Schedule 23 customers, 150 profile meters installed on  
263 irrigation customers, 7 profile meters on Schedule 31 customers, 4 profile meters on  
264 Schedule 21 customers, 262 profile meters on Schedule 8 customers, 167 profile  
265 meters on Schedule 9 customers, 60 profile meters installed on Schedule 135  
266 customers, and 200 profile meters installed on the Utah residential class.

267 In addition, all Utah customers with billed demand equal to or greater than  
268 750 kilowatts have load profile metering installed. Furthermore, at this time there are

269 thirteen Schedule 136 customers with load profile metering installed.

270 **CONCLUSION**

271 **Q. What is your recommendation for the Commission?**

272 A. The Company recommends that the Commission issue an order approving the  
273 Company's proposed plan for gathering load and PG data for the export credit  
274 proceeding. For the export credit proceeding, the Company will have profiles for  
275 exported and delivered energy from all transition customer generators. Having the  
276 profile of exports from the entire population of transition customers ensures that the  
277 Commission will have the opportunity to have a full body of evidence before it by  
278 which to make a decision in the export credit proceeding. Also to further supplement  
279 this information, the Company proposes a study of PG. The Company's plan to study  
280 PG would provide reliable results that are consistent with industry standards. The  
281 overall body of data that would be available from the Company's proposed plan for  
282 the export credit proceeding would be robust and would far exceed that which was  
283 available for the NEM docket.

284 **Q. Does this complete your testimony?**

285 A. Yes.

Utah Customer Generator Load Research Study

February 2018

# **Draft Utah Customer Generator Load Research and Analysis**

**2018**

February 2018

## **Draft Utah Customer Generator Load Research Study February 2018**

### **Introduction**

On December 1, 2017, the Company submitted its application requesting the Commission open a docket to establish determine the compensation rate for exported power from customer generation systems. In order to determine the compensation rate for exported power from private generation (PG) systems, profile data from customer generators is necessary.

As such, this paper describes the procedures to be used in development of the Utah Customer Generator Load Research Study. This study will provide load data that will be used to estimate the appropriate export rate for Utah customer generators.

### **Overview**

The proposed load-research study will result in collecting profiles for energy delivered from the grid to the customer and energy exported from the customer to the grid. This exported data is necessary to accurately calculate the value of energy exported from PG customers. To further supplement the body of data available and to better understand the intertemporal relationship between PG, delivered energy, exported energy, and full requirements energy, the Company proposes a study of PG production.

The proposed load-research study consists of three distinct components, which include: 1) a census of transition program customer-exported energy, 2) a census of transition program customer-delivered energy, and 3) a sample of PG system-energy production from grandfathered net energy metering (“NEM”) customers. The remainder of this document discusses the purpose of this research, analytical needs of the research, participant recruitment, study timeline, and limitations to the research.

### **Export and Delivery**

From a billing perspective, transition customers offset their full requirements usage with energy produced during each 15-minute interval and are billed on their delivered load (15-minute full requirement less energy production). Any PG energy production in excess of full requirements in the 15-minutes creates a bill credit at the export rate (exports).

In order to bill and credit transition customers based upon 15-minute interval data, the Company has begun installing profile meters for each transition customer. This will provide load-research quality data for exports and deliveries for the entire transition customer generator population. As such, it will not be necessary to design a sample of this population, since data for the whole population will be available. One year of transition customer export and delivery data, beginning no later than January 1, 2019 will be relied on for the proposed study.

### **Private Generation Sample**

Although the Company will have export and delivery data for all transition customers, the Company will be required to design a sample to obtain an estimate of PG energy production. At this time, customer specific PG energy production data is not readily available for sample design

purposes. However, the Company believes a reasonable approach for designing a PG sample is to rely on nameplate capacity for residential and non-residential customers.

The distribution of PG nameplate capacities in load studies reveal a large number of customers in the low nameplate categories and relatively smaller amount of customers in higher nameplate categories. When drawing sample customers from the distribution of PG customer, it is necessary to employ a schema that will select customers from across the entire spectrum. The Company's standard practice is to utilize stratified sampling with systematic, random selection. Fundamentally, the sample is divided into several homogenous groups (strata), which in essence translates to low nameplate, medium nameplate, high nameplate, and very high nameplate groups. The recommended sample design for the PG profile will incorporate the use of four strata.

Based on the most recent data available, the July 2017 population of residential and non-residential rooftop solar interconnection agreements, a minimum sample size of 54 PG profile meters are necessary to achieve a precision level of  $\pm 10\%$  at the 95% confidence level.<sup>1</sup> The Company proposes to bolster this minimum sample size requirement by installing a total of 70 PG profile meters (see Table 1). As provided in Table 2, the Company ensured the proposed sample design is representative of the geographic saturation of existing customer generators.

For this research, the Company intends to supplement the 36 PG profile meters that have already been deployed as part of the NEM proceeding.<sup>2</sup> Therefore, the Company intends to install an additional 34 PG profile meters as part of the proposed research. One year of NEM customer PG production data, beginning no later than January 1, 2019 will be relied on for the study.

### **Load Research Participation**

As described in Special Condition 14 of Schedule 136 and in Special Condition 10 of Schedule 135, all randomly selected customers under these rate schedules must participate in any load-research study including the installation of production meters at a mutually convenient location.

### **Timing of Load Research**

The Company will not commence with assigning customers for this study until Commission approval is received. Assuming Commission approval of the load-research study occurs by July 1, 2018, the Company will target full enrollment of customers for the PG sample by December 2018. The study will be based on export, delivery and PG data compiled over a twelve month timeframe, beginning no later than January 1, 2019.

---

<sup>1</sup> PURPA guidelines specify a precision of  $\pm 10\%$  at the 90% confidence level. However, given study design recommendations received from parties to this docket, the Company is proposing a higher level of precision for the sample.

<sup>2</sup> Docket No. 14-035-114 - In the Matter of the Investigation of the Costs and Benefits of PacifiCorp's Net Metering Program.

## Appendix

**Table 1 Utah Residential Transition Program Load Research Study Design**

Strata	Nameplate (kW)	Count	Mean Nameplate (kW)	Squared Nameplate (kW)	Standard Deviation	Required Sample	Supplemented Sample	Currently Installed	Additional Required	Study Total
1	0-6	13,323	4.06	245,161	1.38	14	30	30	0	30
